11.0 PROGRAM RUN TIME 88

1.0 PROGRAM ABSTRACT

DFPTA is the basic device diagnostic for the CI20/NIA20 controller on the KL10. It is intended to detect and isolate hard or stuck at faults in the device. It is used by Manufacturing to repair CI20/NIA20 modules. It is used by Field Service to verify the operation of a port or to isolate a fault to a replaceable module.

DFPTA tests one or two CI20/NIA20 controllers. Each controller consists of three port modules residing in RH20 slot #5 or #7.

DFPTA isolates faults to a network of failing chips. Each network is a set of chips, generally functionally related. Typically, several networks are printed, with the first network being the most probable.

DFPTA consists of two major program sections:

- o Test section - Contains all of the hardware tests. This section is used to debug a module or verify a port.
- o Debug section - Allows detailed manipulation or inspection of the port.

2.0 REQUIREMENTS

2.1 Hardware Requirements

Hardware requirements consist of:

- A KL10, Model B, with at least 93K of memory.
- An CI20/NIA20 Port in RH slot 5 or RH slot 7 or both.
- A load device, such as a KLAD pack.

2.1.1 KL10 Microcode Requirements

The CI20/NIA20 requires special functionality of the KL10 microcode. Therefore, Version 312 or above must be loaded both in user and exec mode.

2.1.2 Memory Requirements

The diagnostic requires 93K of memory of any type. Memory may be configured in any manner, i.e., internal, external, interleaved in any rational manner. The diagnostic's performance is not affected by memory and cache options other than in overall diagnostic run time.

2.1.3 Load Device

The diagnostic loads from any standard load device. Program loading is a function of the standard diagnostic loaders and monitors, i.e., DIAMON, D20MON, MAGMON, KLDCP, etc.

2.2 Software Requirements

Software requirements consist of:

- In exec mode the diagnostic may be loaded by KLDCP, DIAMON, D20MON, or MAGMON. The Subroutine Package must be loaded prior to running the diagnostic.
- In user mode under TOPS-10, release 7.03 or greater is required. DIAMON must be used to load and execute the diagnostic.
- In user mode under TOPS-20, release 6.0 or greater is required. D20MON must be used to load and execute the diagnostic.

2.3 Diagnostic Prerequisites

The diagnostic should only be run after it has been verified that the system has no solid hardware problems of a nature that would render the diagnostic unable to run. This should be determined by first running the following diagnostic programs:

- o CPU and Memory Diagnostics
- o E-Bus Diagnostics
- o C-Bus Diagnostics
- o MAINDEC-10-DFRHB - RH20 Fault Isolator Diagnostic.

3.0 PROGRAM LOADING PROCEDURE

The diagnostic must be loaded via a diagnostic loader program. Refer to loader documentation for instructions on loading and operating the loader program. The diagnostic may be run as a single program or may be chained with other programs using the loader chain feature.

Additionally, in exec mode under KLDCP, the diagnostic may be loaded without using a diagnostic loader program by telling KLDCP to load the diagnostic. This has the advantage of being simpler, but has the disadvantage of inhibiting file handling operations which then prevents use of the TAKE command, and loading of operational microcode by the diagnostic. Loading of operational microcode is required for many of the tests.

4.0 PROGRAM STARTING PROCEDURE

4.1 Starting the Diagnostic

The diagnostic is started in the same manner as most other diagnostics. The diagnostic loader program is run, then the name of the diagnostic, DFPTA, is specified. The loader then loads and starts the diagnostic.

If the diagnostic is already loaded, it may be restarted by a STD or STM in exec mode, or a START or CONTINUE in user mode.

4.2 Initial Program Switches

In exec mode, right hand switches may be selected using the SW command as documented in the KL10 Maintanance Guide under KLDCP. Left hand switches may be selected on the PDP-11 switch panel. If the switches are 0, the diagnostic runs 5 passes of all hardware tests then exits. To allow the user to select which test(s) to run, the left hand switch "OPRSEL" should be set.

In user mode, switches will be queried when the diagnostic starts up. At this point, OPRSEL switch can be set, and any other switches.

In both exec and user mode, switch settings may be altered after the diagnostic has been started.

4.3 Startup Procedure

When the diagnostic is started, the diagnostic name and version number will be printed, followed by a memory map of the system. The diagnostic then looks at RH slots 5 and 7, print what ports are available, and asks the user what ports to test.

If OPRSEL switch is not set, the diagnostic will test every port that exists and is selectable. If this switch is set, the diagnostic will ask what ports to test.

For example (OPRSEL switch not set):

```
D20MON CMD - DFPTA

DFPTA Port Basic Diagnostic
VERSION 0.4, SV=0.15, TOPS-20, KL10, CPU#=1025

SWITCHES = 000000 000000

MEMORY MAP =
FROM     TO          SIZE/K
00000000 00271777      93
```

```
Port Configuration:
  Port  Exists  Selectable  Selected
   NI    Yes       Yes         Yes
   CI    Yes       Yes         Yes

[CI port selected]
[NI port selected]
NI End Pass 1. at 2m 45s
CI End Pass 1. at 5m 29s
NI End Pass 2. at 8m 14s
CI End Pass 2. at 10m 58s
NI End Pass 3. at 13m 43s
CI End Pass 3. at 16m 27s
NI End Pass 4. at 19m 11s
CI End Pass 4. at 21m 56s
NI End Pass 5. at 24m 39s
CI End Pass 5. at 27m 24s

D20MON CMD -
```

For example (OPRSEL switch set):

```
D20MON CMD - DFPTA

DFPTA Port Basic Diagnostic
VERSION 0.4, SV=0.15, TOPS-10, KL10, CPU#=1030

SWITCHES = 000010 000000

MEMORY MAP =
FROM      TO          SIZE/K
00000000 00271777      93

Port Configuration:
  Port  Ex[illegible]  Selectable  Selected
   NI    Y[illegible]       Yes         Yes
   CI    Ye[illegible]      Yes         Yes

Test NI port? (Y [illegible] - N

Test CI port? (Y or N)

[CI port selected]

Type ? for help

What test -
```

The diagnostic asks what device to test, and then asks what test to run. Any test may be selected, or ? or HELP typed to find out what tests are available.

At the end of a test the diagnostic continues at the question "What test -". The next test is selected and run and so on.

4.3.1 Port Configuration

In the "Port Configuration" printout above, "Port Exists" is determined by a CONI. If the "port present" bit is set, then "Port Exists" will be a "Yes". If the port is broken, this bit may not be seen, thereby causing "Port Exists" to be "No". If this happens, the port should be selected for testing anyway.

If "Port Selectable" is "Yes", the port may be selected for testing. Both NI and CI ports are always selectable in exec mode. In user mode a port is selectable only if the diagnostic can take control of the port via a DIAG JSYS.

"Port Selected" is initially "Yes" if the port is selectable. Printing out the configuration at a later time will show which ports have actually been selected.

4.4 Optional Restart Address

Under TOPS-10 or TOPS-20 the diagnostic can be restarted via the "REENTER" command. The program switches are queried, then either testing is begun immediately (if OPRSEL switch is not set) or "What Test - " is asked (if OPRSEL switch is set).

Startup is identical to what occurs if the "START" command is given, except for the DIAMON asking "DIAMON CMD - ".

5.0 PROGRAM STOPPING PROCEDURE

Several methods may be used to stop the diagnostic:

- o Altmode.
- o Control-C.
- o ABORT switch.
- o RSTART switch.

A test can be aborted at any time by typing an altmode on the terminal. When an altmode is typed, the diagnostic is restarted at the test selection routine. At this point, if OPRSEL switch is set, the diagnostic asks what test to run next. If OPRSEL switch is not set the diagnostic runs all tests over again.

Control-C may be typed at any time to stop the diagnostic. To restart, a ''START'', ''CONTINUE'', or ''REENTER'' may be typed in user mode. In exec mode a ''STD'', ''ST'', ''STM'', or ''RN'' may be used.

In exec mode, the ABORT switch may be set, so the diagnostic halts at end of pass.

In exec mode, the RSTART switch may be set. This causes the diagnostic to be restarted, and if OPRSEL switch is set, the diagnostic will have effectively stopped and will be waiting for selection of what test to run.

6.0 PROGRAM OPERATING PROCEDURE

6.1 Overview

The diagnostic is designed to perform repair level testing of the CI20/NIA20 controller.

Essentially, the diagnostic consists of a series of tests which test each of the modules. Some of these are in the form of KL10 based tests using CONO, CONI, DATAO, and DATAIs. The remainder are microcode routines which are loaded into the port CRAM and executed.

6.2 Configuration

When the diagnostic starts up it assumes that a port may be located in RH20 slot #5 or #7. It will select both the possible NI port and the CI port for testing. If user mode, the diagnostic will ask the system for each port. If it does not succeed, it will mark that port as unselectable and will deselect it.

Then the diagnostic prints a port configuration report and asks the user what ports to test. If the port to test has already been selected via switches NIPORT and CIPORT, the diagnostic will not ask.

6.2.1 Configuration Report

The port configuration looks like so:

```
! Port Configuration:
!   Port  Exists  Selectable  Selected
!    NI    No       Yes         No
!    CI    Yes      Yes         Yes
```

This report is printed at diagnostic startup. It can also be obtained at any other time with the command "CONFNT" (Print Configuration), if the switch "OPRSEL" is set.

6.2.2 Configuration Modification

If switch "OPRSEL" is set the selected configuration can be modified using the "SELECT" command to reselect what port to test. Only those ports which are selectable can be selected or deselected.

See Section 10.5.3.2 "Device Selection Commands" for more details concerning this command.

6.2.3 Reconfiguration Capability

If switch "OPRSEL" is set, configuration can be redone using the "CONFIG" command to determine the configuration anew, print out the configuration and ask what port to test.

See Section 10.5.3.2 "Device Selection Commands" for more details concerning this command.

6.3 Choosing Run Time Options

Before starting a test, the diagnostic may ask how many times to execute test selected. If the "OPRSEL" switch is not set this question is not asked, and 5 passes are run on each available port. No other run time options are available, aside from program switch options which are fully described in the Section 7.0 "Program Options (Switches)".

6.4 Modes of Diagnostic Operation

The diagnostic runs in either user mode or exec mode. The operation of the diagnostic is almost identical in either case with the exception of the handling of console switches, speed of operation, and choice of tests to run. The diagnostic runs faster in exec mode for obvious reasons. Also, the PI system is not used in user mode - this means that certain interrupt logic tests do not run in user mode.

In addition, the diagnostic runs with or without user interaction. This is determined by the console switch "OPRSEL". More details may be found in Section 7.0 "Program Options (Switches)".

6.5 Scope Looping

Scope looping is supported by the diagnostic. Several of the program switches described in Section 7.0 "Program Options (Switches)" may be used to cause looping on error and affect error printout when looping.

6.6 General User Interface Philosophy

Decimal numbers are always followed by a point. All other numbers are octal.

All input is preceded with a prompt. All input is checked for legality and incorrect responses are followed by a reprompt and/or an additional error message. All numerical input can be specified as an octal number. Some numerical input may be alternatively given as a decimal number followed by a decimal point. Where the the diagnostic allows multiple input options, a help message is available to explain the options. The diagnostic requests three types of input - numerical, yes or no, and sixbit.

Additionally, the user may obtain a short description of the input expected at any point by typing a question mark followed by a carriage return. The text is printed and the question re-asked.

6.6.1 User Interface

The user interface to the diagnostic is dialogue through the terminal. In exec mode the console switches on the KL are used directly in addition to software switches. In user mode the software switches are used as standard procedure. All user/diagnostic dialogue is done through the diagnostic subroutine package.

6.7 Terminal Input

6.7.1 General

Terminal input is handled by the Subroutine Package. It does not have COMND JSYS style input. However, some control characters are supported. And the diagnostic supports ? and help commands where appropriate to facilitate input.

6.7.2 Control-C Capability (Ctrl-C)

Control-C is used to halt diagnostic execution. In exec mode, control is returned to KLDCP at the ">." prompt. In user mode, the user is returned to monitor level.

When ready to continue, the user may restart or continue the diagnostic in any manner listed previously in Section 5.0, "Program Stopping Procedure". This would be by saying "CONTINUE" in user mode or "RN" in exec mode.

6.7.3 Control-O Capability (Ctrl-O)

Control-O inhibits terminal output. Terminal output resumes when the diagnostic prints some forced output or when the user types another Control-O.

6.7.4 Control-Q Capability (Ctrl-Q)

In exec mode Control-Q is treated as an illegal character by the diagnostic and typing it in response to a question results in an error message.

In user mode Control-Q allows terminal output which may have been inhibited by a prior Control-S. This character may be typed at any time with no other effect than resuming terminal output.

6.7.5 Control-S Capability (Ctrl-S)

In exec mode, Control-S is treated as an illegal character by the diagnostic and typing it in response to a question results in an error message. It may also be typed followed by a carriage return in order to obtain run-time status of the diagnostic.

In user mode, it is used as a terminal output control character along with Control-Q, and has no other function.

6.7.6 Control-T Capability (Ctrl-T)

Control-T is treated as an illegal character by the diagnostic and typing it in response to a question results in an error message in exec mode. In user mode, Control-T gives the current program status and does not interfere with program input.

6.7.7 Control-U Capability (Ctrl-U)

Control-U is used to delete whatever has been typed so far in response to a question. After typing Control-U, the desired input can be entered.

6.7.8 Control-Z Capability (Ctrl-Z)

Control-Z is used to exit from DDT, to either KLDCP in exec mode or to monitor level in user mode.

6.7.9 Question Mark (?)

Question mark may be typed in response to any question. The diagnostic prints a short help message and reprompts the user. If the diagnostic is asking for a test name or a debug command, it prints a list of all valid commands that may be typed.

If a question mark is typed after a legal command, the expected format of the command is given, showing possible arguments.

6.7.10 Altmode (ESC)

Altmode is normally used to abort a test or a sequence of test. If it is given in response to a question, the diagnostic aborts the task which is under way. For example, in DEBUG test, if the user is altering a CRAM location and types altmode in the middle of that, the diagnostic aborts the operation and returns to "DEBUG>" prompt without writing the location.

6.8 Terminal Output

The terminal output generated by the diagnostic consists of:

- Program initialization information
- Program questions/messages
- Test error messages

Much of this output can be affected by program switches, specifically, NOPNT, PNTLPT, TXTINH, and INHMSG.

7.0 PROGRAM OPTIONS (SWITCHES)

Program options are controlled by switches. Left hand switches are predefined but not all are used. Most of the right hand switches are defined specific to the diagnostic.

7.1 Left Hand Switches

In exec mode, left hand switches are modified either via the front end console switches or by using the KLDCP command ESW. See KLDCP documentation for details on the use of the ESW command. Typically, these switches are modified by using the console switches.

In user mode, left hand switches are queried when the diagnostic starts. After that, if the OPRSEL switch is set, switches may be changed using the SWITCH command. The diagnostic will ask for the switches in the same manner as occurred at start up. Also the name of the switch can be typed as a command. This turns the switch on or off depending on its state.

For example:

```
What test - TXTINH

[TXTINH On]

What test - TXTINH

[TXTINH On]

What test - SWPRIN

Switches:  000210 000000   TXTINH OPRSEL

What test - TXTINH

[TXTINH Off]

What test - SWITCH

Print the selectable pgm switches? (Y or N) - N

Switches = 000010 000000

10  LH Switches <# or ?> - 210

0  RH Switches <# or ?> - 0

SWITCHES = 020210 000000

What test - SWPRIN

Switches:  000210 000000   TXTINH OPRSEL
```

7.1.1 Left Hand Switches (Brief Description)

Switch	Symbol	State	Function Description
0 (400000)	ABORT	0	No function.
		1	Abort at end of pass.
1 (200000)	RSTART	0	No function.
		1	Restart diagnostic.
2 (100000)	TOTALS	0	No function.
		1	No function.
3 (040000)	NOPNT	0	Normal typeout.
		1	Inhibit all printing except forced.
4 (020000)	PNTLPT	0	Normal output to TTY.
		1	Print on LPT (user, logical dev).
5 (010000)	DING	0	No function.
		1	Ring bell on error.
6 (004000)	LOOPER	0	Normal operation.
		1	Loop on error.
7 (002000)	ERSTOP	0	Normal operation.
		1	Halt on error.
8 (001000)	PALERS	0	Print only first error in loop.
		1	Print all errors.
9 (000400)	RELIAB	0	No function.
		1	Reliability mode switch.
10 (000200)	TXTINH	0	Print full error messages.
		1	Short error messages.
11 (000100)	INHPAG	0	KL - allow 4096K addressing.
		1	KL - inhibit paging.
12 (000040)	MODDVC	0	No function.
		1	Modify device codes.
13 (000020)	INHCSH	0	Use cache.
		1	Inhibit using cache on pgm start.
14 (000010)	OPRSEL	0	Run default operations.
		1	Operator test selections.
15 (000004)	CHAIN	0/1	Used by ''DIAMON'', etc. to control

			chain operations.
16 (000002)	Unused	0 1	KA10 60 Hertz power KA10 50 Hertz power
17 (000001)	Unused		Reserved

7.1.2 Left Hand Switches (Detailed Description)

The following is a detailed description of each console data switch function:

Switch 0 (ABORT)

When this switch is set, the diagnostic returns control to the diagnostic loader at end of pass.

Switch 1 (RSTART)

When this switch is set while a test is being executed, the diagnostic aborts testing after completion of the current test, and restarts the diagnostic.

Switch 2 (TOTALS)

Setting this switch has no effect on diagnostic operation.

Switch 3 (NOPNT)

This switch inhibits all printout except forced. Forced printout is used with questions requiring user response. This switch is useful when it is desired to force a test to run without printing error information. To suppress the remainder of a current error report, type a Control-O on the terminal. This suppresses the remaining error information for the current error and allows printing to start again for the next error.

Switch 4 (PNTLPT)

When this switch is zero, all printouts from the diagnostic are printed on the terminal. If set only forced printouts are printed on the terminal. All data, including forced printouts, is printed on the line printer.

Switch 5 (DING)

This switch causes the terminal bell to be rung when an error occurs.

Switch 6 (LOOPER)

This switch causes error looping within a test. Looping occurs in the first failing test. The diagnostic continues to loop on the test or a portion thereof even if it stops failing, until the LOOPER switch is reset or an altmode is typed.

Switch 7 (ERSTOP)

This switch causes the diagnostic to terminate testing when an error occurs. If the OPRSEL switch is set the diagnostic will continue at the 'What Test -' prompt. If the OPRSEL switch is not set the diagnostic will exit and return control to the diagnostic loader.

Switch 8 (PALERS)

Normally an error message is printed only the first time an error occurs if that error is being repeated continuously. To print all occurrences of every error, set this switch.

Switch 9 (RELIAB)

If this switch is set, each test is run 4 times before control is passed to the next test selected. If only one test has been selected, the test would be run 4 times the repeat count given for the test.

Switch 10 (TXTINH)

If this switch is not set, complete data is printed with each error message. If this switch is set, less data is printed in a shortened form.

Switch 11 (INHPAG)

This switch inhibits paging if set and allows it if not set.

Switch 12 (MODDVC)

If this switch is set, DIAMON asks for any device code modifications. This is not used by the diagnostic itself.

Switch 13 (INHCSH)

This switch, if set, inhibits the use of cache during the time the diagnostic is run. This switch is inspected only in exec mode and only at diagnostic start up. Changes of the switch setting do not affect the cache after the diagnostic has started up.

Switch 14 (OPRSEL)

If set, this switch enables increased user interaction. The diagnostic asks explicitly what test or function to do before doing anything. Test selection is made in response to the question:

```
What Test? -
```

At least enough letters to recognize the test selection must be typed although up to six letters are accepted. "?" may be typed to get a list of the test names or commands. "HELP" may be typed to get a short description of each test or command.

If this switch is not set, the diagnostic runs 5 passes of all hardware tests on each port, prints fault isolation data (if the inhibit fault isolation switch is not set), then exits.

Switch 15 (CHAIN)

This switch is used by DIAMON/D20MON in chaining operations and is not used by the diagnostic in normal operation.

Switch 16 (50CYC) - Unused

This switch is used on KA10s to select 50 Hertz power. It is not used by this diagnostic.

Switch 17 - Unused

This switch is reserved for use by the diagnostic monitor or subroutine package and is not used by the diagnostic.

7.2 Right Hand Switches

7.2.1 Right Hand Switches (Brief Description)

Switch	Symbol	State	Function Description
18 (400000)	TRACE	0	Normal operation.
		1	Trace operation of tests.
19 (200000)	INHFLT	0	Normal operation.
		1	Inhibit fault isolation.
20 (100000)	INHMSG	0	Normal operation.
		1	Inhibit error message printout.
21 (040000)	LOOPGM	0	Normal operation.
		1	Loop on program.
22 (020000)	LOOPTS	0	Normal operation.
		1	Loop on selected test.
23 (010000)	RUNALL	0	Normal operation.
		1	Run all segments of each test.
24 (004000)	DSPEAR	0	Normal operation.
		1	Disable SPEAR error reporting.
25 (002000)	UDEBUG	0	Normal operation.
		1	Diagnostic debug mode.
26 (001000)	MDEBUG	0	Normal operation.
		1	Error message debug mode.
27 (000400)	SDEBUG	0	Normal operation.
		1	Test execute debug mode.
28 (000200)	LDEBUG	0	Normal operation.
		1	Inhibit loading of test microcode.
29 (000100)	IDEBUG	0	Normal operation.
		1	Fault isolation debug mode.
30 (000040)	NIPORT	0	Do not specifically select NI port for testing.
		1	Select NI port for testing.
31 (000020)	CIPORT	0	Do not specifically select CI port for testing.
		1	Select CI port for testing.
32 (000010)	Unused		
33 (000004)	Unused		

34 (000002)	MMPROC	0 1	The MPROC module is inserted. The MPROC module is not inserted.
35 (000001)	MCBUS	0 1	The CBUS module is inserted. The CBUS module is not inserted.

7.2.2 Right Hand Switches (Detailed Description)

Switch 18 (TRACE)

This switch is used if the user wants to follow test progress. As each test is started, the diagnostic prints the name of the test and the current PC. This is useful to gain assurance that the diagnostic is running or to find out what test it died on, if the diagnostic fades into oblivion.

The names of all tests selected are printed. If the test has been disabled or if it is one the the tests that cannot be run in user mode, the test name is printed followed by the phrase "(Disabled)". Tests that run in exec mode only will be followed by the phrase "(Exec mode only)" when running in user mode.

Switch 19 (INHFLT)

If set, this switch inhibits fault isolation. All selected tests are run even if the fault isolation algorithm indicates that the test need not be run. Fault isolation data may still be obtained; however, the result is probably not be as valid.

If not set, only those tests are run which the fault isolation algorithm determines should be run.

Switch 20 (INHMSG)

This switch is used to run the diagnostic with all normal printout except error messages. It can be used in place of "NOPNT" switch when looping on an error.

Switch 21 (LOOPGM)

If this switch is not set and OPRSEL switch is not set, the diagnostic runs 5 passes of all tests. Then the diagnostic returns to DIAMON or D20MON or KLDCP.

If this switch is set and OPRSEL switch is not set, the diagnostic runs all tests continuously, pass after pass.

If OPRSEL switch is set, the diagnostic asks "What Test - " to determine what test to run. When done with a test, the diagnostic returns to this question. The LOOPGM switch is not used.

Switch 22 (LOOPTS)

This switch allows a specified test to be looped on forever. It is equivalent to specifying "EB22 37777777777" to run test EBUS test 22 a very large number of times. This switch may be overridden by specifying an explicit repeat count.

This switch is effective only when selecting a single test. If a class of tests is selected, the switch is ineffective.

If this switch is not set the default repeat count when selecting a specific test is 1 repetition.

Switch 23 (RUNALL)

This switch forces every segment of a test to be run. Normally, a test exits after the first error, unless looping on error. To force the diagnostic to run every segment of the test regardless of error, this switch may be set.

This switch has no effect if LOOPER switch is set and the diagnostic is looping on an error.

Switch 24 (DSPEAR)

This switch enables or disables SPEAR error reporting. If the switch is not set, the diagnostic will make two SPEAR entries - (1) an entry when the diagnostic is started and (2) an entry either upon first error or at end of pass if no errors have occurred.

If the switch is set, no SPEAR entries will be made. If the diagnostic has already started, the second entry will not be made.

Switch 25 (UDEBUG)

This switch allows the diagnostic to be run in user mode without a port for the purposes of diagnostic development or debug or for the purpose of familiarization with the diagnostic without affecting or requiring a port.

If this switch is set, the diagnostic runs every test as demanded. All tests and most commands in the DEBUG test appear to succeed.

Switch 26 (MDEBUG)

This switch forces every test to fail and prints out an error message for each failure. This may be used to debug error messages, or familiarize a person with typical error printouts of this diagnostic. It can also be used when trying to diagnose a failing test which passes the first few test segments - this switch causes error messages to be printed for passing portions of the test so that it can be seen what the port is doing correctly, without looking through the diagnostic listing.

Switch 27 (SDEBUG)

This switch is used for diagnostic debug purposes. If set, each table entry of a table driven test is printed as the test is executed.

Switch 28 (LDEBUG)

The first action of any test is normally to load the microcode required by the test. Setting this switch inhibits the automatic loading of microcode. This allows test microcode to be modified using the DEBUG facility and the test to be rerun.

Switch 29 (IDEBUG)

This switch is used to debug the fault isolation algorithm. If set, the possible faulty networks and probably good networks are printed at various stages during testing.

If not set, testing occurs as usual, with the usual amount of printout.

Switch 30 (NIPORT)
Switch 31 (CIPORT)

When the diagnostic determines the hardware configuration, it finds out if what ports exist and whether or not each can be selected for testing. In exec mode a port can be selected whether or not it appears to exist. In user mode the diagnostic must be able to successfully request the port from the system in order to determine that the port is selectable.

If neither switch is set, the diagnostic will ask what ports to test.

If at least one of the switches is set, the diagnostic will select the port or ports specified whether or not it appears to exist, unless the port cannot be selected (user mode only). The diagnostic will not ask the use whether or not the port should be tested.

Switch 32 - Unused

Switch 33 - Unused

Switch 34 - MMPROC

This switch, when set, is used to indicate to the diagnostic that the Microprocessor control module is not inserted. No tests which require use of that module are run.

If this switch is not set, the diagnostic runs any test which requires at least an EBUS and MPROC module, but not a CBUS module. If neither this switch nor MCBUS switch is set, tests using any module may be run.

Switch 35 - MCBUS

This switch, when set, is used to indicate to the diagnostic that the CBUS module is not inserted. No tests which require use of that module are run.

If this switch is not set, the diagnostic runs all tests, depending only on the state of Switch 34.

8.0 ERRORS

This section describes the operation of the diagnostic upon encountering various types of errors. There are basically three types:

- User input errors
- Hardware errors
- Unexpected errors

8.1 User Input Errors at the Terminal

The diagnostic requests three types of input: numerical, yes or no, and SIXBIT. The action taken upon input error is as follows:

When an error is detected on numerical input the diagnostic prints an error message describing the type of error. Then it either asks the question again, or returns to "What test -" or "DEBUG>".

When an error is detected on a yes or no input, the user is merely reprompted, until a Y or N is typed.

When an error is detected on SIXBIT input an error message is printed and the user is asked the question again. The user can then ask the diagnostic for further information by asking for help or typing "?".

8.2 Error Reporting of Hardware Detected Errors

Upon the occurrence of a hardware error a full error description is printed, depending on the setting of switches "NOPNT", "PNTLPT", "TXTINH", and "INHMSG".

If the diagnostic is looping on error only the first occurrence of an error is printed. Subsequent errors at the same place are not printed. If the "DING" switch is set, the terminal bell is sounded to indicate that an error was detected, even though nothing is printed.

8.2.1 Reporting to SPEAR

The diagnostic makes 2 SPEAR entries. The first is an entry when the diagnostic is started. This entry contains the date, time, user, diagnostic name and version. A second entry is made when the first error occurs. This entry contains the date, time, user, diagnostic name and version, failing test name and test description.

If the diagnostic completes a successful pass with no errors, it will make the second entry as above, but there will be no test name or test description included.

If, thereafter, an error occurs and the diagnostic has already made an entry indicating successful completion of a pass, the diagnostic will make one more entry, giving the error information.

Whenever the diagnostic is restarted by an STM or reloaded and restarted, it will make entries into the system error file. If the 2 entries have already been made, restarting via a STD or CONT will not result in additional entries.

SPEAR entries can be disabled using the switch "DSPEAR".

8.2.2 Error Printouts

Errors are printed as they occur in a standard form. Where appropriate, the CSR register or LAR register contents is printed. A sample printout with TXTINH switch not set follows:

```
+-+-+-+-+-+-+
? CI Error:  TEST CB1-1 - Fmtr Data Loopback
Test PC = 222"  Scope PC = 237"  Switches = 020010 000000
Data loopback through Fmtr failed (result in EBUF)
Start Addr:  0000 , # Steps:  6.
End Addr - Correct:  5004
             Actual:  4002
EBUF - Correct:  777777 777777
        Actual:  000000 230014
-------------
```

This error printout gives the following data:

- Port indication - CI.
- Test name - CB1-1 (CBUS test #1 segment #1), name of test is "Fmtr Data Loopback".
- Test PC - 222" - address of the start of the test. Note that this is a relative address as will be found in the test listing.
- Scope PC - 237" - address which can be found in the diagnostic listing of the call to the scope loop routine. Note that this is a relative address also.
- Switches - those in effect at the time of the error printout.
- "Data loopback through Fmtr failed (result in EBUF)" - description of error.

- Test related information such as
  - Starting CRAM address - 0000
  - Number of single steps done - 6.
- Error information such as
  - Where the test should have stopped (CRAM address 5004) and where it actually did (CRAM address 4002)
  - EBUF data correct and actual

If TXTINH is set, the printout looks like:

```
+-+-+-+-+-+-+
? CI Error:  TEST CB1-1  Scope PC 237"  SW 020210 003020
Start  0000 , # Steps  6.
End (C):  5004
    (A):  0000
EBUF (C):  777777 777777
     (A):  000000 230014
-------------
```

8.3 Unexpected Errors

The diagnostic is written to recover from any usual error condition and continue testing. However, there are a few halts coded into the diagnostic to catch a completely lost program because of some unexpected malfunction:

ADDRESS	REASON
1011	Fatal push list pointer error
1012	Initial push list pointer error
1013	MUUO with LUUO handler wiped out
1014	DTE20 interrupt without doorbell
1015	DTE20 clock interrupt without flag set
1016	CPU initialization error
1017	End of program error
1020	Interrupt with LUUO handler wiped out

The diagnostic is coded with several fatal instructions which cause

Fatal program error at address xxxxx

to be printed and the diagnostic to halt. These instructions are placed where the diagnostic finds itself in a situation where it does not know how to proceed. There are no anticipated program deficiencies that allow a fatal error to be executed.

9.0 PROGRAM DESCRIPTION

This section provides a functional overview of the diagnostic, giving information concerning requirements and restrictions, fault detection and isolation, error handling, terminal input and output characteristics, and diagnostic applications.

9.1 Program Overview

9.1.1 Program Purpose

DFPTA is a basic device diagnostic intended to detect and isolate hard or stuck at faults for the CI20/NIA20 controller on the KL10. It tests only CI20/NIA20 controllers consisting of 3 port modules located in RH20 slots #5 and #7.

9.1.2 Testing Strategy

The diagnostic attempts to run simpler tests first that exercise a small amount of logic. Then more and more testing is done, until the tests are exercising much of the logic of the port at once. First, the EBUS interface is tested, then other portions of the EBUS module. Then, the data path used in loading microcode is tested. Then, microcode is loaded and the 2910 sequencer is tested. Then, more of the EBUS module is tested including the 2901s. Then, more of the MPROC module. Then, the CBUS internal data path, followed by the channel interface, followed by the rest of the CBUS module.

If test tracing is being done, it will be noted that the tests are not run in numerical sequence.

If fault isolation is disabled (the INHFLT switch is set), the diagnostic runs each test in numerical sequence - EBUS tests, then MPROC tests, then CBUS tests.

9.2 Run-Time Dynamics

9.2.1 Memory Allocation Requirements

The diagnostic loads and executes in less than 96K of memory. This includes the memory used by the diagnostic monitor (DIAMON or D20MON or MAGMON) and the subroutine package (SUBRTN or SUBUSR or SUBKL).

9.2.2 Operating System Interactions

9.2.2.1 TOPS-10

The diagnostic runs under TOPS-10 release 7.03 and later using the DIAG. UUO. The diagnostic requests and releases the port using the DIAG. UUO.

The diagnostic can only be run if the port is not being used by the operating system. This is done in a single CPU environment by dismounting any mounted structures on all HSC50s. In a multiple CPU environment, other CPUs will have access to the disks attached to HSC50s using their CI20 ports, so the structures need not be dismounted.

The CI port is made available for diagnostic use by the OPR program's "CONFIG REMOVE CI-n" command, where "n" is the CPU number.

9.2.2.2 TOPS-20

The diagnostic interfaces with TOPS-20 via the DIAG JSYS. The diagnostic requests the port using the DIAG JSYS. When done, the diagnostic releases the device also using the DIAG JSYS.

The diagnostic can only be run if the port is not being used by the operating system. The DIAG JSYS will succeed only if this is so. Hence, the user must close all CI connections before running this diagnostic.

On TOPS-20 the CI is used for data transfer with HSC50 based disks and for communication with other TOPS-20 systems. Communication over the CI is required for operation under CFS-20 (TOPS-20 Common File System). Under TOPS-20 release 6.1 and later, Phase IV DECnet-20 communications to other TOPS-20 systems may be active over the CI.

The CI is removed from operating system use by dismounting all mounted structures on any HSC50 and closing all other communications over the CI. This is accomplished via the OPR program's "SET PORT CI UNAVAILABLE" command.

9.2.3 User Mode Restrictions

None.

9.2.3.1 User Mode Privileges

Under TOPS-20 a user must have at least MAINTENANCE privileges in order to run the diagnostic. Users with WHEEL or OPERATOR capability also have sufficient privileges to run the diagnostic.

Under TOPS-10, you must be running as [1,2] or have privileges to execute the TRPSET and DIAG. UUOs.

9.2.3.2 User Mode Priority Interrupts

The diagnostic is not allowed to use the Priority Interrupt System in user mode. In user mode, the diagnostic polls the CSR Register for interrupt conditions.

9.3 Exec Mode Capability

The diagnostic runs in exec mode under KLDCP or, additionally, under DIAMON or MAGMON. All tests are capable of being run in exec mode.

9.4 User Mode Capability

The diagnostic runs in user mode under TOPS-20 (release 6.0 or newer) and TOPS-10 (release 7.03 or newer). There are no restrictions imposed upon the diagnostic in user mode.

9.5 Fault Detection

9.5.1 Error Resolution

The diagnostic isolates faults to a network of failing chips. Each network is a set of chips, generally functionally related. Typically, several networks are printed, with the first network being the most probable.

9.5.2 Fault Detection And Isolation

The purpose of the diagnostic is to diagnose hard faults on the CI20/NIA20 Controller and to isolate those faults to a specific failing field replaceable unit (FRU). The diagnostic testing is performed by a bottom up testing technique. This is accomplished by performing a basic operation and then using that verified logic to verify the functionality of more logic.

The diagnostic should detect 99% of solid faults in the port modules and isolate 95% of these to the FRU.

9.5.3 Fault Detection

Typically, the diagnostic detects a fault, then prints it out and continues testing. When done the failing module is called out followed by a list of failing networks.

Occasionally, particularly with EBUS interface failures, the diagnostic may just hang, or the KL10 microcode may hang. This may happen if the port cannot complete an EBUS operation such as an examine or deposit properly. If this occurs, no error message or module callout is printed. The solution is to restart the diagnostic and run the tests over again with the test tracing switch, "TRACE", set. Then, the failing test can be observed. From this point, the diagnostic listing for the test should be inspected to see what is being done. If the port was executing microcode at this time, the LAR can be read and microcode single stepped to duplicate the failure.

9.6 Network Descriptions

9.6.1 EBUS Module networks

9.6.1.1 E1 - EBUS Control Logic

This consists of most of the control logic on page EBI1 which does DATAI, DATAO, CONI, CONO decoding, IOP decoding, and interrupt handling.

9.6.1.2 E2 - CC EBUS RQST

This is located on page EBI1 and consists of the control logic driving the condition code "EBI1 CCEBUSRQST".

9.6.1.3 E3 - CC GRNT CSR

This is located on page EBI1 and consists of the control logic driving the condition code "EBI1 CCGRNTCSR" and several related signals "EBI1 MPRQSTCSRLTCH" and "EBI1 PORTGRNTCSR".

9.6.1.4 E4 - Interrupt Logic

This is located on page EBI2, labelled "Interrupt Generation Logic". Also included is two related pieces of logic on the same page which drive the signals "EBI2 LOADEBUS" and "EBI2 XFER".

9.6.1.5 E5 - Clock Logic

This consists of the inverters on page EBI2 from which come clocks 1 and 3.

9.6.1.6 E6 - Clear Logic

This is located on page EBI2, and consists of the logic driving the signals "EBI2 CLREBUF", "EBI2 CLEARA" and "EBI2 CLEARB". Also included is a bit of logic on page EBI4 which determines "EBI4 CSR18".

9.6.1.7 E7 - Magic # Field Decode

This is located on page EBI2.

9.6.1.8 E8 - CC CSR CHNG

This is located on page EBI2, and consists of the logic which drives the condition code "EBI2 CCCSRCHNG".

9.6.1.9 E9 - KMUX

This is located on page EBI3, labelled "KMUX". Also included is the enable logic on page EBI2, "EBI2 ENAKMUX", "EBI2 EBPAROUT", and "EBI2 EBPARACT".

9.6.1.10 E10 - EMUX

This is located on page EBI3, labelled "EMUX". Also included is the enable on page EBI2, "EBI2 ENAEMUX".

9.6.1.11 E11 - RMUX/CSR 25-31

This is located on page EBI4, and consists of the control logic driving CSR bits 25-31 and the RMUX (labelled appropriately). There is also a gate on page EBI2 which is included, which is 'EBI2 RMUXLOADCSR''.

9.6.1.12 E12 - CSR 11-13/19-22/33-35

This is located on page EBI4, and consists of the control logic driving CSR bits 11-13, 19-23 and 33-35.

9.6.1.13 E13 - CSR 04 Rqst Exam/Dep

This is located on page EBI4, and consists of the control logic driving the signal 'EBI4 CSR04''.

9.6.1.14 E14 - CSR 05 Rqst Interrupt/CC INTR ACTIVE

This is located on page EBI4, and consists of the control logic driving the signals 'EBI4 CSR05'', 'EBI4 MPROCERR'', 'EBI4 CLRRUN'', and 'EBI4 CCINTRACTIVE''.

9.6.1.15 E15 - CSR 06/07 CRAM PE/MBUS Error

This is located on page EBI4, and consists of the control logic driving the signals 'EBI4 CSR06'' and 'EBI4 CSR07''.

9.6.1.16 E16 - CSR 24 EBUS PE

This is located on page EBI4, and consists of the control logic driving the signals 'EBI4 CSR24'' and 'EBI4 CCEBPARERR''.

9.6.1.17 E17 - CSR 32 MPROC Run

This is located on page EBI4, and consists of the control logic driving the signal 'EBI4 CSR32''.

9.6.1.18 E18 - KMUX Parity Generation

This is located on page EBI5, and consists of 5 parity generators, the output of which is "EBI5 KMUXPAR H".

9.6.1.19 E19 - EBUS Parity Checking

This is located on page EBI5, and consists of 5 parity generators, the output of which is "EBI5 EBPARERR H".

9.6.1.20 E20 - EBUF

This is located on page EBI5, labelled "EBUF".

9.6.1.21 E21 - EBUS Data Xcvrs

This is located on the top half of page EBI6, and consists all of the EBUS transceivers carrying data signals.

9.6.1.22 E22 - EBUS Control Xcvrs

This is located on the bottom half of page EBI6, and consists all of the EBUS transceivers carrying control signals.

9.6.1.23 E23 - 2901s/Carry Logic

This occupies all of pages EBI7 and EBI8.

9.6.1.24 E24 - Constant MUX

This is located on page EBI9, labelled "CNST MUX".

9.6.2 MPROC Module networks

9.6.2.1 M1 - MPROC Run Clocks

This is located on page MPR1, labelled "uPROC Run Clocks". Also included are the 'MPR1 CLK1A, CLK2A, CLK3A, CLK4A" also on page MPR1. Also, 'MPR1 CSR32" and 'MPR1 Error" are grouped in this category.

9.6.2.2 M2 - Local Memory Control

This is located on page MPR1, labelled "Local Memory Control".

9.6.2.3 M3 - MBUS Error Detect Logic

This is located on page MPR2, labelled 'MBUS Error Detect Logic". Also included are two inverters on page MPR1 'MPR1 EnaEMUX" and 'MPR1 EnaCMUX".

9.6.2.4 M4 - CRAM Read/Write Control

This is located on page MPR2, labelled "CRAM Read/Write Control". Also included is some inverters on MPR1 which fan out some of the cram control signals.

9.6.2.5 M5 - Jump ADDR MUX

This is located on page MPR3, labelled "Jmp MUX".

9.6.2.6 M6 - CC MUX

This is located on page MPR3, labelled "CC MUX".

9.6.2.7 M7 - 2910 MicroSequencer

This is located on page MPR3, labelled 'MICROSEQR".

9.6.2.8 M8 - CRAM ADDR MUX

This is located on page MPR3, labelled "Addr MUX".

9.6.2.9 M9 - LAR

This is located on page MPR3, labelled "LAR". Loading the LAR requires the signal "MPR1 LOADLAR" which is located on page MPR1. The logic involved with this is included in this category.

9.6.2.10 M10 - CRAM 0000-7777

This consists of all of the 4k x 4 rams on pages MPR4 and MPR5.

9.6.2.11 M11 - Cond/Skip Decoder

This is located on page MPR6, labelled "Cond/Skip Decoder".

9.6.2.12 M12 - CRAM Control Register

This occupies all of page MPR7, labelled "CRAM Ctrl Reg". Also included here are the parity checkers for this register, located on page MPR6, labelled "CRAM Par Chkr".

9.6.2.13 M13 - Local Storage RAM

This is located on page MPR8, labelled "Local Store".

9.6.2.14 M14 - Local Storage Addr Register

This is located on page MPR8, labelled "Loc Stor Addr Reg". In addition, the signal "MPR1 CLKSADREG" is included, on page MPR1.

9.6.2.15 M15 - RAM Mode MUX

This is located on page MPR8, labelled "RAM Mode MUX".

9.6.2.16 M16 - RAR

This is located on page MPR9, labelled "RAR".

9.6.2.17 M17 - Right CRAM Load Buffer

This is located on page MPR9, labelled "Right CRAM Load Buff".

9.6.2.18 M18 - Left CRAM Load Buffer

This is located on page MPR9, labelled "Left CRAM Load Buff".

9.6.2.19 M19 - MW Out MUX

This is located on page MPRA, labelled "MW Out MUX".

9.6.3 CBUS Module networks

9.6.3.1 C1 - CBUS Control Logic

This consists of the logic which controls the operation of the channel, including the logic which cycles through the select, request, wait, and data states and the logic which handles the "MPSTORECBUS" and "MPWRITEMEM" signals. This is found on pages CBI1, CBI2, and CBI5.

9.6.3.2 C2 - Clock Logic

This is located on page CBI1, labelled "Clock Generation Logic".

9.6.3.3 C3 - Reset Logic

This is found on page CBI1, a group of inverters with the output signal "CBI1 Reset L".

9.6.3.4 C4 - Clear Logic

This is found on page CBI2, two inverters and two nand gates with the input signal "MPR1 ClearA L".

9.6.3.5 C5 - "CC CBUS AVAIL"

This consists of the logic which implements this condition code and it is located on page CBI2.

9.6.3.6 C6 - "CC CB LST WD"/ "CC CHAN ERR"

This consists of the logic which implements these condition codes and it is located on page CBI2.

9.6.3.7 C7 - "CLR CC CODE"

This is found on page CBI2, having the output signal "CBI2 ClrCCCode L".

9.6.3.8 C8 - Magic # Field Decode

The magic number field is decoded on page CBI3. This logic occupies most of this page. A few inverters are also shown on page CBI4 - "CBI4 EnaCMUXA" and "CBI4 PlinToCMUXA".

9.6.3.9 C9 - "CC CBUS PAR ERR"

This consists of the logic which implements this condition code and it is located on page CBI3.

9.6.3.10 C10 - "CC PLI PAR ERR"

This consists of the logic which implements this condition code and it is located on page CBI3.

9.6.3.11 C11 - Parity Predictor

This is located on page CBI4, labelled "Parity Predictor".

9.6.3.12 C12 - Formatter Control

This is located on page CBI4, labelled "Formatter Control".

9.6.3.13 C13 - PLI Control Logic

This is located on page CBI4, labelled "PLI Ctrl Logic".

9.6.3.14 C14 - CBUS Input Buffer

This is located on page CBI5, labelled "CBUS Input Buffer".

9.6.3.15 C15 - CBUS Output Buffer

This is located on page CBI5, labelled "CBUS Output Buffer".

9.6.3.16 C16 - CBUS Out Par Gen

This is located on page CBI6, labelled "CBUS Out Par Gen".

9.6.3.17 C17 - CBUS In Par Checker

This is located on page CBI6, labelled "CBUS In Par Checker".

9.6.3.18 C18 - DMUX

This is located on page CBI7, labelled "DMUX".

9.6.3.19 C19 - SMUX

This is located on page CBI7, labelled "SMUX".

9.6.3.20 C20 - Mvr/Fmtr

This is located on page CBI8, labelled "Mvr/Fmtr".

9.6.3.21 C21 - PLI Logic

This occupies most of page CBI9, labelled "PLI Par Input Checker", "PLI Par Output Generator", and "PLI Output Buffer".

9.6.3.22 C22 - PMUX

This is located on page CBI9, labelled "PMUX".

9.6.3.23 C23 - CMUX

This is located on page CBIA, labelled "CMUX".

9.6.3.24 C24 - CBUF

This is located on page CBIA, labelled "CBUF".

9.7 Performance During Hardware Failures

9.7.1 CPU/Memory Failures

Most CPU and memory faults are fatal errors to the diagnostic and it does not continue after one.

9.7.2 Power Fail/Restart

If a power fail occurs, the diagnostic must be reloaded and rerun when the system is back in operation.

9.7.3 Port Failure

Hardware failure in the port is anticipated and results in an error message.

9.7.4 Unexpected Traps

The diagnostic can fail due to an unexpected malfunction. Sometimes an error code is printed, if the subroutine package intercepts the error. Other cases may result in a hung diagnostic or CPU or occasionally a fatal error message. See the Section 8.3 "Unexpected Errors" for more details.

9.8 Program Applications

The diagnostic can be used for coarse determination of a fault - does the port work and if not what module is broken.

It can also be used for detailed examination of a port.

9.8.1 Users and Uses

The diagnostic is generally used only by Manufacturing to assist module construction and debug, and by Customer Services when determining the FRU of a failing port.

9.8.2 Engineering Usage

Engineering used this diagnostic for breadboard debug, design verification, and for prototype debug and maintenance. Engineering may use the diagnostic if any ECOs are made in the future.

9.8.3 Manufacturing Usage

This diagnostic is used by Manufacturing as part of the acceptance procedure for an CI20/NIA20. It is also used to repair faulty port modules (EBus Interface, Micro-Processor Control, and CBus Interface modules).

9.8.4 Customer Services Usage

Customer Services uses the diagnostic as part of acceptance procedure, when an CI20/NIA20 is sent to a customer in a drop ship environment. Customer Services also uses this during CM and PM.

9.8.5 Customer Usage

With the exception of OEM customers, it is not likely that any customers will use the diagnostic. If they have a problem with the port they notify Customer Services who can then run the diagnostic. OEM customers, running the diagnostic themselves, would interface to their account sales representative if any difficulties arose or problems discovered.

9.9 Test Design

The basic design of most tests is as follows:

- o Do something to the port.
- o Inspect the results.
- o If error, print an error message.

- If error and error looping enabled, loop on error.

This fits into the diagnostic as described by the following steps done by the diagnostic:

- Do program initialization
- Select test category
- Run these tests
  - Select a test
  - Run it
  - Select next test, exit if no more
- Select next test category to test if OPRSEL switch is set, otherwise exit the diagnostic.

9.9.1 Type of Tests

There are three types of tests:

- Hardware Test
- Program Option Selection
- Debugger Test

Whenever the tests are run without manual control of which test is selected, only hardware tests are run. This is the major function of the diagnostic and these tests comprise 95% of the diagnostic.

Program option selection tests can be selected when manual control of what test to run has been selected. These are not tests in that they do not do anything to the hardware. But since they are selected from a list of hardware tests, they are called tests. These consist of switch selections or changes, help, and exit commands.

The debugger test is a special test that allows one to to CONI, CONO, DATAI, and DATAOs to the port and in effect write ones own test. The purpose of this test is for hardware debug of the port, where one is interested in doing things and inspecting the results in a less formal fashion than just running tests. This is only one test but it allows many different things to be done to the port. It is intended to be used primarily in breadboard debug, but may be used later by Customer Services or Manufacturing.

9.9.2 Test Flow

If only one port is being tested, all of the tests specified are run on the port. Then fault isolation data is printed if any errors occurred.

If both NI and CI ports are being tested simultaneously, the diagnostic runs all of the tests on the NI first, printing fault isolation data afterwards. Then all of the tests are run on the CI following by printing fault isolation data.

The following sections describe starting and stopping tests.

9.9.2.1 Starting the Test

After the program switches have either been given via console switches or by typing them in on the terminal, the diagnostic starts the tests as selected by the switches or by user input.

If test tracing is enabled, the diagnostic prints the test pc and test name at the beginning of each test, and a phrase such as "(Disabled)" or "(Exec mode only)" if the test actually is not going to be run.

A test is disabled if such has been specified with the DISABLE test command. A test is inhibited only in user mode where the test cannot be run because it uses the PI system or causes page faults. There are about 15 of these tests.

9.9.2.2 Stopping the Test

A test sequence may stop either by terminating normally, by halting on error (if the ERSTOP switch is set), by the user setting the ABORT or RSTART switches, or by typing an Altmode or C. In user mode, ABORT and RSTART are ignored if set.

The diagnostic continues at one of several places depending on switch settings and whether or not the diagnostic is being run in exec or user mode and what loader has been used to load the diagnostic:

- o D20MON CMD -
- o DIAMON CMD -
- o MAGMON CMD -

- What Test -
- . (TOPS-10 prompt)
- @ (TOPS-20 prompt)
- o >. (KLDCP prompt)

9.9.2.3 Obtaining Run Time Status (Control-T)

In user mode the current program status is given when T is typed. This is not available in exec mode.

9.9.2.4 Obtaining Run Time Status (S or Control-S)

In exec mode, while running tests, the current test name and time is printed when an S <CR>, s <CR> or Control-S is typed.

In user mode, typing an S or s produces the printout.

10.0 TEST DESCRIPTIONS

10.1 Test Description Assumptions

All test descriptions assume that no program switches are set. The action of a test if a particular switch is set may be determined by reviewing the function of the switch, given in prior sections.

10.2 Test Description Overview

The description for "program option selection" test consists of what each item does and a description of its use.

The description given for a "hardware" test consists of a single line test description. The diagnostic listing provides a detailed description at the beginning of each test. Specific implementation details can be obtained from the listing or from the microcode of the test.

The description for the "debug" test gives a list of commands and what each does.

10.3 Program Option Selections

10.3.1 Basic Description

This is a set of commands that can be given to facilitate running tests or debugging the port.

10.3.2 Commands Available

The commands available in regular mode are as follows, which are typed in response to the prompt 'What test - ':

Hardware tests:

NAME	DESCRIPTION
ALL n	All tests (n times)
EBUS n	EBus module tests
SEQ n	SEQ related tests
ALU n	2901 related tests
MPROC n	MPROC module tests
CBUS n	CBus module tests
MBUS n	MBUS related tests
XXm n	Test m, category XX (where XX can be EB,SE,AL,MP,CB)

General Commands:

NAME	DESCRIPTION
HELP	Print this message
EXIT	Return to normal test dispatching
DDT	Enter DDT (Type RTN$X to return)
TAKE	Take cmds from file
NTAKE	Take cmds from file (not echoed)
DEBUG	Enter port debugger
DIAMON	Enter DIAMON

Test Control Commands:

NAME	DESCRIPTION
ENABLE n	Enable execution of test n
DISABL n	Disable execution of test n
DISLIS	List disabled tests
LIST n	List all tests (or just test n)
LISTEB n	List EBus module tests (or test n)
LISTSE n	List Sequencer related tests
LISTAL n	List 2901 related tests
LISTMP n	List MPROC module tests
LISTCB n	List CBus module tests

Device Selection Commands:

CONFIG	Determine/print configuration
CONPNT	Print configuration
SELECT	Select device to test

Switches:

SWITCH	Enter switch information
SWPRIN	Print current switch settings

NOPNT	Complement "no print" switch
PNTLPT	Complement "print lpt" switch
DING	Complement "bell on error" switch
LOOPER	Complement "loop on error" switch
ERSTOP	Complement "halt on error" switch
PALERS	Complement "print all errors" switch
RELIAB	Complement "reliability mode" switch
TXTINH	Complement "text inhibit" switch
OPRSEL	Complement "operator select" switch

TRACE	Complement "trace test" switch
INHFLT	Complement "inhibit fault isolation" switch
INHMSG	Complement "inhibit error message" switch
LOOPGM	Complement "loop on pgm" switch
LOOPTS	Complement "loop on test" switch
RUNALL	Complement "run all test segments" switch
DSPEAR	Complement "disable SPEAR reporting" switch
UDEBUG	Complement "user mode debug" switch
MDEBUG	Complement "error message debug" switch
SDEBUG	Complement "test debug" switch
LDEBUG	Complement "load microcode debug" switch
IDEBUG	Complement "fault isolation debug" switch
NIPORT	Complement "Select NI port" switch
CIPORT	Complement "Select CI port" switch
MPROC	Complement "missing MPROC module" switch
MCBUS	Complement "missing CBUS module" switch

10.3.3 Detailed Command Description

In more detail these commands are as follows:

10.3.3.1 Hardware Tests

ALL n

This command will run all hardware tests the number of times specified by the repeat count. If no repeat count is specified, the diagnostic asks how many passes to run.

If fault isolation is not inhibited, fault isolation data will be printed upon completion of the tests. If testing is aborted by typing an altmode, the fault isolation data is printed at that point.

EBUS n

This command will run all EBUS module tests in the same manner as ALL above. This includes the 2901 ALU testing.

SEQ n

This command will run all 2910 micro-sequencer tests in the same manner as ALL above.

ALU n

This command will run all 2901 ALU tests in the same manner as ALL above.

MPROC n

This command will run all MPROC module tests in the same manner as ALL above.

CBUS n

This command will run all CBUS module tests in the same manner as ALL above.

MBUS n

This command will run all MBUS cable related tests in the same manner as ALL above. The diagnostic also prints a short description of how to debug an MBUS problem. This description follows:

```
To isolate a possible MBUS problem:

 (1) Disconnect MBUS cable from EBUS module.
     Run MBUS tests with MMPROC and MCBUS switches set.
     Failed - EBUS module is at fault.  Stop.
     Passed - MBUS cable or MPROC or CBUS modules at fault.
              Continue at next step to isolate further.

 (2) Connect MBUS cable to EBUS module only.
     Run MBUS tests with MMPROC and MCBUS switches set.
     Failed - MBUS cable is at fault.  Stop.
     Passed - MBUS cable or MPROC or CBUS modules at fault.
              Continue at next step to isolate further.

 (3) Connect MBUS cable to EBUS and MPROC modules only.
     Run MBUS tests with MCBUS switch set.
     Failed - MPROC module is at fault.  Stop.
     Passed - CBUS module at fault.  Stop.
```

XXm n

This command is given to run a single test. The test name is given as a 1 or 2 letter test category followed by the test number. The test categories and sample test names are as follows:

o Ebus module test ..... EB10 or E10

o 2910 Sequencer test .. SE10 or S10

o 2901 ALU test .... AL10 or A10

o MPROC module test .... MP10 or M10

o CBUS module test ..... CB10 or C10

A repeat count may be given. If not given, the test is executed only once.

10.3.3.2 General Commands

HELP

This command prints a one line description for each command.

EXIT

This command returns control to the diagnostic loader or to KLDCP if no loader program was used to load the diagnostic in exec mode.

DDT

This command invokes DDT. When RTN$X (POPJ 17,0) is executed, the diagnostic resets the PI system in exec mode and returns to 'What Test - " question. DDT can also be entered by typing Control-D and when done typing RTN$X. When invoked in this fashion, the diagnostic does not reset the PI system.

TAKE file ext

This command takes commands from a file. The file may be specified as an argument to the command. If no file name is specified, the default file name is used. The default file name is either 'DFPTA.CMD" or the last file specified.

Any legal command may be specified except another TAKE or commands which cause exit from the diagnostic such as DDT or DIAMON or EXIT. DIAMON or EXIT may be included but processing of the take file will terminate with the command. The diagnostic prints each command and result on the terminal as it executes each command.

The file specified must be on the load device known to MAGMON or D20MON or DIAMON. If not, an error message is printed and the take command is aborted.

If any error occurs while processing the take file, the take command is aborted. Errors include any unexpected errors such as unrecognized command, failures to start the port, argument errors, etc.

NTAKE file ext

This command is identical to the TAKE command with the single exception that the commands executed are not echoed on the terminal. All output resulting from execution of the commands is echoed.

DEBUG

Enter port debugger. This test allows specific operations to be done with the port without the restrictions of executing a particular test.

DIAMON

Enter DIAMON. This is the same as the EXIT command if a diagnostic loader is present. If MAGMON is loaded instead of DIAMON, control returns to MAGMON.

10.3.3.3 Test Control Commands

ENABLE n,n,n,... and DISABL n,n,n,...

The running of a particular test can be explicitly prevented with the DISABL command. The ENABLE command allows the execution of the specified tests to be enabled again. Disabling a test will guarantee that the test will not be run. Enabling a test will allow a test to be run, but whether or not it is run, depends on the determination made by the fault isolation algorithm and the availability of the required port modules.

Test names are given as "Test Class" "Test Number". where test class is:

- SE or S - 2910 sequencer tests
- MP or M - Mproc module tests
- AL or A - 2901 ALU tests
- CB or C - CBus module tests
- EB or E - EBus module tests

Sample test names are SE1, SE27, EB1, E1, AL20, ...

Example:

```
What test - ENABLE EB3,EB4
What test - DISABL EB3,EB4,S2,SE70,AL10,A11
```

DISLIS

This command lists what tests have been disabled. Example:

```
What test - DISLIS

EB1 EB3 EB4 SE1 SE2 MP1 MP2
```

LIST n

List all tests (or just test n). This command prints the test description which is also printed in each error message. If no argument is given, all test descriptions are printed (this can be aborted by typing an altmode). If a test name such as MP2 is typed, only the description for that test will be printed. Example:

```
What test - LIST EB2

EB2 - RH20/Port Interaction

What test - LIST

EB1 - CONI Works?
EB2 - RH20/Port Interaction
EB3 - RH20/Port Interaction
...
```

LISTxx n,n

Test descriptions can be selected for printing within a class. A command of the form "LIST" followed by the "test class" code specifies tests within the test class. The commands are as follows:

- LISTEB n,n - List EBus module tests (or test n)
- LISTSE n,n - List Sequencer related tests
- LISTAL n,n - List 2901 related tests
- LISTMP n,n - List MPROC module tests
- LISTCB n,n - List CBus module tests

Up to 2 numeric arguments may be given which are decoded as follows:

- o No arguments - all tests are listed.
- o One argument - such as 'LISTSE 4' - list only the specified test (in this example it is test SE4).
- o Two arguments - such as 'LISTSE 4,10' - list tests 4 through 10 in the selected test class.

Example:

```
What test - LISTSE 4,5

SE4 - JZ Instruction - Effect on Reg/Ctr
SE5 - CONT Instruction

What test - LISTMP

MP1 - CRAM Data Test RAR12=0
MP2 - CRAM Data Test RAR12=1
...
```

10.3.3.4 Switches

SWITCH

Enter switch information. Switches can be entered as in the following example. Usually, though, it is easier just to type the switch name to turn on or off a switch.

```
What Test - SWITCH

Print the selectable pgm switches? (Y or N) - Y

----Left Side Switches--------     ----Right Side Switches--------

SW   KL10     11     Function      SW   Value   Function
--   ----    ----    --------      --   -----   --------
 0  400000  100000   Abort         18  400000   Program trace
 ...

Switches = 020010 004000

20010  LH Switches <# or ?> - ?

Type  Y,N,^,CR,^Z

N ABORT -
N RSTART -
...
```

```
4000  RH Switches <# or ?> - ?

Type  Y,N,^,CR,^Z

N TRACE -
N INHFLT -
...
```

SWPRIN

Print current switch settings. Example:

```
What Test - SWPRIN

Switches:  020010 002000   PNTLPT OPRSEL UDEBUG
```

```
NOPNT    RELIAB   TRACE    DSPEAR   UDEBUG
PNTLPT   TXTINH   INHFLT   NIPORT   MDEBUG
DING     OPRSEL   INHMSG   CIPORT   SDEBUG
LOOPER            LOOPGM   MPROC    LDEBUG
ERSTOP            LOOPTS   MCBUS
PALERS            RUNALL
```

The name of each of these switches can be typed. The result is to complement the switch setting. If left hand switches are typed in exec mode an error message is printed.

10.4 Hardware Tests

More information on each of the following hardware tests listed here can be found in the program listing.

10.4.1 Hardware Tests - EBUS Module

10.4.1.1 EBUS Interface Tests

EB1 - CONI Works?
EB2 - RH20/Port Interaction
EB3 - RH20/Port Interaction
EB4 - RH20/Port Interaction
EB5 - RH20/Port Interaction

10.4.1.2 CSR Register Tests

EB6 - CSR Cleared After Reset
EB7 - Read/Write CSR Bits
EB10 - CSR Bits Interaction

10.4.1.3 EBUF Tests (MBus Loopback)

EB11 - EBUF Access Test
EB12 - EBUF/CSR Conflict Test
EB13 - KMUX Parity Generators
EB14 - EBUF/CSR Conflict Test
EB15 - EBUF Reset Test
EB16 - EBUF Data Path Test

10.4.1.4 CSR Bit 18 "Clear Port" Tests

EB17 - CSR Bit 18 Self Clearing Test
EB20 - CSR Bit 18 Reset Test
EB21 - CSR Bit 18 Reset Test

10.4.1.5 'Diag Test Ebuf''/Initialized

EB22 - Read/Write EBUF When Ucode Running

10.4.1.6 Parity Generators/Checkers Tests

EB23 - Par Gen - Not Forcing an Error
EB24 - Par Gen - Forcing an Error

10.4.1.7 CSR Read Only Bits

EB25 - Read only CSR Bits

10.4.1.8 CSR 01 ''DIAG RQST CSR''

EB26 - CSR 01 ''DIAG RQST CSR''
EB27 - CSR 01 ''DIAG RQST CSR''
EB30 - CSR 01 ''DIAG RQST CSR''
EB31 - CSR 01 ''DIAG RQST CSR''
EB32 - CSR 01 ''DIAG RQST CSR''
EB33 - CSR 01 ''DIAG RQST CSR''

10.4.1.9 CSR 02 ''DIAG CSR CHNG''

EB34 - CSR 02 ''DIAG CSR CHNG''

10.4.1.10 Contant MUX

EB35 - Constant MUX
EB36 - Constant MUX Interference
EB37 - CSR Bit 24 - EBUS PE Occurs at Wrong Time
EB40 - EBUS Transfer via DATAOs
EB41 - EBUS Transfer via DATAIs

CB53 - Parity Predictor - CBIN to Fmtr/MPINDSTCOMP=0
CB54 - Parity Predictor - CBIN to Fmtr/MPINDSTCOMP=1
CB55 - Parity Predictor - Fmtr to PLOUT
CB56 - Parity Predictor - PLIN to Fmtr/MPCOREDUMP=0
CB57 - Parity Predictor - PLIN to Fmtr/MPCOREDUMP=1

CB60 - Parity Predictor - Fmtr to CBOUT

10.5 Debug Test

10.5.1 Basic Description

This test allows the selection of different operations that may be done on port. In some cases, probably rarely, a field engineer may wish to diagnose an port by doing particular operations. More often this type of testing may be useful when repairing individual modules if the technician doing the repair is very familiar with the module and how it works. This test provides the ability to perform a basic operation such as writing a register or doing something with microcode and then inspecting the results to see what happened.

Normally, the port tests provide sufficient detection and isolation of faults to fix the port. Occasionally, a person trying to fix the port may encounter an unusual problem not detected by the diagnostic or having strange symptoms. This test may allow some understanding of the problem to be gained.

This test can also be used to debug microcode using the breakpoint facilities. And it can be used to run small microcode routines of the user's own devising.

10.5.2 Commands Available

The commands available in debug mode are as follows, which are typed in response to the prompt 'DEBUG> ':

```
NAME          DESCRIPTION
----          -----------

General Commands:
-----------------

HELP          Print this message
EXIT          Exit DEBUG mode
DDT           Enter DDT (Type RTN$X to return)

SET opt arg     Set/clear/print options
TAKE file ext   Take commands from a file
NTAKE file ext  Take commands from file (unechoed)

Device Selection Commands:
--------------------------

CONFIG        Determine/print configuration
CONPNT        Print configuration
SELECT        Select device to test

Starting, Stopping, Initializing the Port:
------------------------------------------

RESET         Issue EBUS Reset
CLEAR         Issue a "Port Clear"
```

START adr	Start the port micro-sequencer
STOP	Stop the port micro-sequencer
CONT	Continue the port micro-sequencer
SSTEP cnt	Single step the port micro-sequencer
STRACE cnt	Single step and trace execution
SPRINT cnt	Print single step history data
SCLEAR	Clear single step history data
SSINIT	Set up single step addr/data/history

Handling Port Registers:

ECSR	Examine CSR Register
DCSR dat	Deposit CSR Register
ZCSR	Zero CSR Register
EEBUF	Examine EBUF register
DEBUF dat	Deposit EBUF register
ZEBUF	Zero EBUF register
ELAR	Examine LAR register
DRAR dat	Deposit RAR register
ZRAR	Zero RAR register

Handling Port CRAM Locations:

The next few commands must have at least one argument and possibly two. Two arguments give the range of CRAM address to be altered or inspected. If only one argument is given the range is only one location. If the deposit command is given, the diagnostic will ask what to deposit into each location.

DCRAM adr,adr	Deposit into CRAM
BCRAM adr,adr	Deposit into CRAM by fields
ACRAM adr,adr	Alter CRAM
ECRAM adr,adr	Examine CRAM
LCRAM adr,adr	List CRAM
ZCRAM adr,adr	Zero CRAM

2901 Commands:

E2901 reg,reg	Examine 2901 registers
D2901 reg,dat	Deposit 2901 register
Z2901 reg,reg	Zero 2901 registers

Local Storage Commands:

ELOCS adr,adr	Examine local storage
DLOCS adr,dat	Deposit local storage
ZLOCS adr,adr	Zero local storage

Special Scope Functions:

```
     -----------------------

     LCONI       Loop on CONI
     LCONO dat   Loop on CONO
     LDATAI      Loop on DATAI
     LDATAO dat  Loop on DATAO
     LROUTN dat  Loop on user supplied routine at DROUTN:

     Mark Bit Commands:
     -----------------

     MARK adr,adr   Set mark bit
     RMARK adr,adr  Remove mark bit
     CMARK adr,adr  Clear all mark bits
     LMARK adr,adr  List mark bits

     Breakpoint Commands:
     -------------------

     BREAK adr,adr   Set breakpoint
     RBREAK adr,adr  Remove breakpoint
     CBREAK adr,adr  Clear all breakpoints
     LBREAK adr,adr  List breakpoints
     PBREAK adr      Proceed from breakpoint
     WBREAK          Print breakpoint data

     Microcode Commands:
     ------------------

     LOAD tst    Load microcode from Test "tst" into CRAM
     LIST tst    List microcode from Test "tst"
     FLOAD       Load microcode from file into CRAM
     FVERFY      Verify microcode loaded from file
     FLIST       List microcode in file
     FEXAM       Examine microcode in file

     Miscellaneous Commands:
     ----------------------

     TRANSL dat  Translate data to CSR bits
     CCODE       Print condition codes
     ESTACK      Examine 2910 stack contents
     FILLNX dat  Fill CRAM with "J=.+1,CTL=dat"
     FILLPC dat  Fill CRAM with "J=.,CTL=dat"
     ENEXT       Examine next
     DNEXT arg   Deposit next

     IPRINT      Print accumulated interrupt activity
     ICLEAR      Clear accumulated interrupt activity
     IINIT       Init interrupt system

     Data Transfer Commands:
     ----------------------

     RDINIT    Initialize everything for a read
     WRINIT    Initialize everything for a write
```

BPRINT n	Print buffer contents (n locations)
CCWPNT	Print CCW list
LOGPNT	Print logout data
COMPAR	Compare data buffer

Switches:

SWITCH	Enter switch information
SWPRIN	Print current switch settings
NOPNT	Complement "no print" switch
PNTLPT	Complement "print lpt" switch
DING	Complement "bell on error" switch
LOOPER	Complement "loop on error" switch
ERSTOP	Complement "halt on error" switch
PALERS	Complement "print all errors" switch
RELIAB	Complement "reliability mode" switch
TXTINH	Complement "text inhibit" switch
OPRSEL	Complement "operator select" switch
TRACE	Complement "trace test" switch
INHFLT	Complement "inhibit fault isolation" switch
INHMSG	Complement "inhibit error message" switch
LOOPGM	Complement "loop on pgm" switch
LOOPTS	Complement "loop on test" switch
RUNALL	Complement "run all test segments" switch
DSPEAR	Complement "disable SPEAR reporting" switch
UDEBUG	Complement "user mode debug" switch
MDEBUG	Complement "error message debug" switch
SDEBUG	Complement "test debug" switch
LDEBUG	Complement "load microcode debug" switch
IDEBUG	Complement "fault isolation debug" switch
NIPORT	Complement "Select NI port" switch
CIPORT	Complement "Select CI port" switch
MPROC	Complement "missing MPROC module" switch
MCBUS	Complement "missing CBUS module" switch

10.5.3 Detailed Command Description

In more detail these commands are as follows:

10.5.3.1 General Commands

HELP

This command prints a one line description similar to the above for each command.

EXIT

This command returns control to normal test dispatching at the 'What Test -' question.

DDT

This command invokes DDT. When RTN$X (POPJ 17,0) is executed, the diagnostic resets the PI system in exec mode and returns to 'DEBUG>' question. DDT can also be entered by typing Control-D and when done typing RTN$X. When invoked in this fashion, the diagnostic does not reset the PI system.

SET

This command is used to set, clear, or print program options. The option is specified as the first argument and the option setting as the second argument. The options that may be dealt with are as follows:

- SET ADDR adr.

  This command sets the start address of the microsequencer. Whenever a START command or a SSINIT command is given, the default address given here is used. A START command may also explicitly specify the starting address. No commands other than SET ADDR alter the default starting address.

  The initial default address is location 0. To find out the current default address, type SET ADDR <CR>.

- SET CSR data.

  This command sets the initial CSR register starting contents. When a subsequent START or SSINIT command is given, this data is written to the CSR when starting the microsequencer. This allows the state of CSR bits to be set up - such as interrupt enable and PI level bits.

  The initial value is 0. When a START or single step command is given with the default CSR data equal to 0, the diagnostic writes 14 to the CSR register (MPRUN, PI Level 4) or 20014 if single stepping (SINCYC bit included).

  To find out the current start data, type SET CSR <CR>.

- SET PARITY arg.

  This command affects the automatic parity generation when loading microcode into the CRAM. If the flag is "YES" the diagnostic computes correct parity before it loads any microcode. If "NO" the diagnostic assumes the parity has already computed and does not alter the parity bit specified in the microcode data.

This flag only affects microcode explicitly loaded in the DEBUG test. This flag does not affect loading microcode from a file. When operational microcode is loaded in this fashion, parity is not affected.

The initial value of the flag is "YES". To find out the current setting, type SET PARITY <CR>.

o SET EBUF arg.

This command affects the automatic preservation of the EBUF when single stepping or stopping the microsequencer. If "preserve EBUF" flag is "YES" the diagnostic will read the EBUF before reading the LAR and then write back the data afterwards. If the flag is "NO" the contents of the EBUF will be destroyed every time the RAR is written or the LAR read.

The initial value of the flag is "YES". To find out the current setting, type SET EBUF <CR>.

o SET LENGTH len.

This command sets the buffer length to be used when generating CCW lists. Any length up to 102400 (decimal) words may be specified. However, note that the buffer is only 512 words long and each CCW in the CCW list points to the same starting location. This is so that a 512 word buffer can be used and much longer data transfers can be specified.

The initial length is 128 words. To find out the current setting, type SET LEN <CR>.

o SET PAT n.

This command specifies the data pattern to be used by commands which generate CCW lists and set up buffer contents and do buffer compares. Any data pattern from 1 to 126 (octal) may be entered.

The initial value is 1 (data pattern zeros). To find out the current setting, type SET PAT <CR>.

o SET PATLIS arg,arg.

This command prints what data patterns are available. One or two arguments may be given to specify a range of data patterns. The diagnostic prints a description for each data pattern in the range specified. If no arguments are specified, all data patterns will be printed.

o SET FNAME name ext

The diagnostic allows a microcode file to be loaded into CRAM or listed on the terminal. The commands used do not allow a microcode file name to be specified. The name of the file used can be changed by this command.

The initial file name is "CI20.ULD". To find out the current setting, type SET FNAME <CR>.

- SET WHAT

  This command prints the current selection of each option.

- SET HELP

  This command prints a help message describing each option available to the set command.

TAKE file ext

This command takes commands from a file. The file may be specified as an argument to the command. If no file name is specified, the default file name is used. The default file name is either "DFPTA.CMD" or the last file specified.

Any legal command may be specified including another TAKE command. The presence of a TAKE or DDT or EXIT (from DFPTA) command in the take file will terminate use of the current file. The diagnostic prints each command and result on the terminal as it executes each command.

The file specified must be on the load device known to MAGMON or D20MON or DIAMON. If not, an error message is printed and the TAKE command is aborted.

If any error occurs while processing the take file, the TAKE command is aborted. Errors include any unexpected errors such as unrecognized command, failures to start the port, argument errors, etc.

NTAKE file ext

This command is identical to the TAKE command with the single exception that the commands executed are not echoed on the terminal. All output resulting from execution of the commands is echoed.

10.5.3.2 Device Selection Commands

CONFIG

This command causes the diagnostic to reconfigure. It determines whether or not an NI or CI port exists, and if each is selectable by the diagnostic. Then the configuration is printed and the port(s) to test are queried as follows:

```
| Port Configuration:
|   Port  Exists  Selectable  Selected
|    NI    Yes       Yes         Yes
|    CI    Yes       Yes         Yes
```

```
Test NI port? (Y or N) - N

Test CI port? (Y or N) - Y

[CI port selected]
```

CONPNT

This command prints the configuration determined at last configuration as modified by any selection of ports to test. For example:

```
Port Configuration:
  Port  Exists  Selectable  Selected
   NI    Yes       Yes         No
   CI    Yes       Yes         Yes
```

SELECT port,port

This command allows the current selection of ports to be modified. There are two alternate formats for this command. First, SELECT <CR> will cause the diagnostic to query which port to select as follows:

```
What test - SELECT

Test NI port? (Y or N) - N

Test CI port? (Y or N) - Y

[CI port selected]
```

The selection may be stated in the SELECT command by typing SELECT NI <CR> or SELECT CI <CR> or SELECT NI,CI <CR>. An example follows:

```
What test - SELECT NI,CI

[NI port selected]
[CI port selected]
```

10.5.3.3 Starting, Stopping, Initializing the Port

The START, SSTEP or STRACE commands can be given at any time without concern if the port is running or not. The diagnostic will stop the port if it has to and clear any error condition. If it changes the state of the port, the diagnostic prints a message to that effect.

RESET

Issue EBUS Reset. This does a COND APR,200000. In user mode a "Port Clear" is done instead.

CLEAR

Issue a "Port Clear". A 400000 is written to the CSR register.

START adr

The port is started at address specified. The procedure is as follows:

- o Determine start address. If no address is specified, the start address used is the default address given by the SET ADDR command.
- o Determine start CSR data. This is the data specified by a SET CSR command. Insert the necessary bit "MPRUN" and ensure "SINCYC" bit is not set.
- o Read the CSR register, if the port is already running or error bits are set, stop the port or clear error bits as necessary.
- o Write the start address to the RAR
- o Write CSR data to the CSR

CONT

This command is identical in function to the START command with the exception of the start address. In addition, if the port is not already stopped, an error message is printed and the start sequence aborted. The start address is the last "next" address obtained from a single step command.

The only purpose of this command is to start up the port after single stepping it for a while.

STOP

Stop the port micro-sequencer and print out the contents of the LAR. If the CSR is inaccessible, or if error bits CRAM PE or MBUS Error are set, an error message is printed.

SSTEP n and STRACE n

Single step the port micro-sequencer "n" times. Before this command is done the first time, the start data and start CSR data must be set up using the SSINIT command. Thereafter, the address written to the RAR each time the port is single stepped is the "last address" read from the LAR after the prior single step.

STRACE causes the single step history data to be printed at the same time that single steps are being done. The data is printed in the same format as the SPRINT command except for the order in which the single steps are printed.

The port is stopped or error bits are cleared from the CSR register as necessary before any single steps are done.

If CRAM PE or MBUS Error bits become set in the CSR register, a message is printed and the single stepping is aborted.

To abort the single step procedure at any time, type altmode.

SPRINT n

Print single step history data. Data for the last "n" (maximum 128) single steps are printed in the following format. If no argument is given, no more than 20 single steps are printed.

```
DEBUG> SPRINT 4

 RAR   LAR   CSR (final)   SS#
0000  0100  000000 020010  12
0100  0230  000000 020010  11
0230  0231  000000 020010  10
0231  0232  000000 020010  7
```

SCLEAR

Clear single step history data.

SSINIT

Set up single step data. This sets the single step address to be the default address specified by the SET ADDR command. The single step CSR data is set to the default data specified by the SET CSR command. Also, the single step history data is cleared.

This command MUST be given in order to execute the first single step. If not given the port will start at the last address executed by a single step.

10.5.3.4 Handling Port Registers

Each of the EBUF commands can be given at any time without concern if the port is running or not. The diagnostic will stop the port if it has to and clear any error condition. If it changes the state of the port, the diagnostic prints a message to that effect.

ECSR

Examine CSR Register. The contents are printed in octal and translated into English as well.

DCSR dat

Deposit CSR Register. The data expected is up to 6 octal digits.

ZCSR

Zero CSR Register. This also stops the port if it is running.

EEBUF

Examine EBUF register. The data is printed in halfword format.

The port is stopped or error bits are cleared from the CSR register as necessary before reading the EBUF. Then the "Test EBUF" bit is set in the CSR register if it is not already set and the EBUF is read.

DEBUF dat

Deposit EBUF register. The data expected is up to 12 octal digits.

The port is stopped or error bits are cleared from the CSR register as necessary before reading the EBUF. Then the "Test EBUF" bit is set in the CSR register if it is not already set and the EBUF is written.

ZEBUF

Zero EBUF register

The port is stopped or error bits are cleared from the CSR register as necessary before reading the EBUF. Then the "Test EBUF" bit is set in the CSR register if it is not already set and the EBUF is zeroed.

ELAR

Examine LAR register and print it as "LAR/ 0000". This is actually a 13 bit register. The right most bit is the bit written to the RAR register to specify which half of the CRAM to access. This bit is not printed.

DRAR dat

Deposit RAR register. The data consists of a 12 bit CRAM address followed by one bit specifying left or right half. Example:

```
¦ DEBUG> DRAR 0           ; Write location 0 (right half)
¦ DEBUG> DRAR 1           ; Write location 0 (left half)
¦ DEBUG> DRAR 10          ; Write location 4 (right half)
¦ DEBUG> DRAR 11          ; Write location 4 (left half)
```

ZRAR

Zero RAR register.

10.5.3.5 Handling Port CRAM Locations

Each of the following commands can be given at any time without concern if the port is running or not. The diagnostic will stop the port if it has to and clear any error condition. If it changes the state of the port, the diagnostic prints a message to that effect. The diagnostic also ensures that "Test EBUF" bit is not set and "Sel LAR" bit is not set.

Commands that read or write CRAM locations are given up to 2 arguments. The action in each case is as follows:

- No arguments - The CRAM addresses used are those last used. So if a zero CRAM command is given to clear locations 1001 through 1004, a subsequent examine cram command with no arguments would examine locations 1001 through 1004.
- One argument - The range of CRAM locations is taken as addr1,addr1.
- Two arguments - The range of CRAM locations is taken as addr1,addr2.

DCRAM adr,adr

Deposit into CRAM locations specified either by explicit arguments or by default. The format of the data is the same format produced as output of the MICRO2 assembler. Example:

```
DEBUG> DCRAM 10

Type xxxx,xxxx,xxxx,xxxx,xxxx
0010 ::   11,22,33,44,55
```

BCRAM adr,adr

Deposit into CRAM locations specified either by explicit arguments or by default. The data is asked for each location, one field at a time. The initial data to be written to each CRAM location is zero. Example:

```
DEBUG> BCRAM 10

Type  value,value... or ^,CR,^Z,field name
0010 ::
J -
PAR -               Type:  value<CR> value<CR> ...
```

```
|  OENA -                 or:  value,value,...<CR>
|  MGC -                  or:  ^ to back up to the previous
|  SORC -                          value
|  FUNC -                 or:  <CR> to leave a value unchanged
|  DEST -                 or:  field name such as MGC or FUN or
|  CENA -                          A or M (for MGC) .. to skip to
|  RAM -                           a particular field
|  A -                    or:  ^Z to terminate input and store
|  B -                             the CRAM location
|  SK -                   or:  $ (altmode) to abort the command
|  BUS -                           and not store anything
|  CRY -
|  CTL -
|  TIME -
|  SPARE -
|  MARK -
```

Note: Everything can be typed on one line, such as this example to change A, B, and MGC fields only:

```
|        DEBUG> BCRAM 10
|
|        Type  value,value... or ^,CR,^Z,field name
|        0010 ::
|        J - A,3,4,M,1234,^Z
|
|        DEBUG>
```

ACRAM adr,adr

Alter CRAM locations specified either by explicit arguments or by default. The data is asked for each location, one field at a time. Example:

```
|  DEBUG> ACRAM 10
|
|  Type  value,value... or ^,CR,^Z,field name
|  0010 ::
|  0 J -
|  0 PAR -                 Type:  value<CR> value<CR> ...
|  0 OENA -                  or:  value,value,...<CR>
|  33 MGC -                  or:  ^ to back up to the previous
|  0 SORC -                           value
|  1 FUNC -                  or:  <CR> to leave a value unchanged
|  0 DEST -                  or:  field name such as MGC or FUN or
|  0 CENA -                           A or M (for MGC) .. to skip to
|  0 RAM -                            a particular field
|  0 A -                     or:  ^Z to terminate input and store
|  0 B -                              the CRAM location
|  22 SK -                   or:  $ (altmode) to abort the command
|  0 BUS -                            and not store anything
|  1 CRY -
|  0 CTL -
|  0 TIME -
|  0 SPARE -
```

```
:  0 MARK -
```

Note: Everything can be typed on one line, as in the example under "BCRAM" command above.

ECRAM adr,adr

Examine CRAM locations specified either by explicit arguments or by default. The data is printed in MICRO2 assembler format. Example:

```
!  DEBUG> ECRAM 10,12
!
!  0010 / 0000 0001 0400 0000 0400
!  0011 / 0000 0001 1400 0000 0440
!  0012 / 0000 0001 2400 0000 0500
```

LCRAM adr,adr

List CRAM locations specified either by explicit arguments or by default. The data is printed in bit field format. Example:

```
!  DEBUG> LCRAM 0,3
!
!  ADDR/ JUMP PAR OUT MGC SOR FUN DES CC RAM PA PB SK BUS CRY CTL  TM SP MK
!     0/    0  0   0    0  0   1   0   0  0   0  0  0  0   0  JZ    0  0  0
!     1/    0  0   0    0  0   3   0   0  0   0  0  0  0   0  JZ    0  1  0
!     2/    C  0   0    0  0   5   0   0  0   0  0  0  0   0  JZ    0  2  0
!     3/    0  0   0    0  0   7   0   0  0   0  0  0  0   0  JZ    0  3  0
```

ZCRAM adr,adr

Zero CRAM locations specified either by explicit arguments or by default.

10.5.3.6 2901 Commands

Each of the following commands can be given at any time without concern if the port is running or not. The diagnostic will stop the port if it has to and clear any error condition. If it changes the state of the port, the diagnostic prints a message to that effect.

These commands may be given up to 2 arguments. The action in each case is as follows:

- o No arguments - The 2901 registers used are those last used. So if registers 0 through 4 are examined, a subsequent examine command with no arguments would examine registers 0 through 4.

- o One argument - The range of 2901 registers is taken as reg1,reg1.
- o Two arguments - The range of 2901 registers is taken as reg1,reg2

E2901 reg,reg

Examine the contents of the range of 2901 registers specified. Microcode is loaded into the port to accomplish this, but no 2901 registers or local storage locations are affected. And the original contents of the CRAM location used are restored.

D2901 reg,data

Deposit the data into the 2901 register specified. Microcode is loaded into the port to accomplish this, and only the 2901 register specified is affected. The original contents of the CRAM location used are restored.

To deposit data into successive registers, additional data can be typed. For example, to load registers 3,4,5,6 with 333,444,555,666 respectively, type the following:

```
DEBUG> D2901 3,333,444,555,666
```

Z2901 reg,reg

Zero the range of 2901 registers specified. Microcode is loaded into the port to accomplish this. The original contents of the CRAM location used are restored.

10.5.3.7 Local Storage Commands

Each of the following commands can be given at any time without concern if the port is running or not. The diagnostic will stop the port if it has to and clear any error condition. If it changes the state of the port, the diagnostic prints a message to that effect.

These commands may be given up to 2 arguments. The action in each case is as follows:

- o No arguments - The local storage addresses used are those last used. So if a zero local storage command is given to clear locations 101 through 104, a subsequent examine local storage command with no arguments would examine locations 1001 through 1004.

- o One argument - The range of local storage locations is taken as addr1,addr1.
- o Two arguments - The range of local storage locations is taken as addr1,addr2

ELOCS adr,adr

Examine local storage addresses specified by the range of addresses. Microcode is loaded into the port to accomplish this and several 2901 registers are destroyed in the process. No local storage locations are affected. And the original contents of the CRAM locations used are restored.

DLOCS adr,dat

Deposit local storage address "adr" with 36 bit octal data "dat". Microcode is loaded into the port to accomplish this and several 2901 registers are destroyed in the process. No local storage locations are affected. And the original contents of the CRAM locations used are restored.

To deposit data into successive locations, additional data can be typed. For example, to load locations 103,104,105,106 with 333,444,555,666 respectively, type the following:

```
DEBUG> DLOCS 103,333,444,555,666
```

ZLOCS adr,adr

Zero local storage addresses specified by the range of addresses. Microcode is loaded into the port to accomplish this, but no 2901 registers or local storage locations are affected. And the original contents of the CRAM locations used are restored.

10.5.3.8 Special Scope Functions

These commands allow scope loops to be set up for only doing a CONI, CONO, DATAI, or DATAO. The diagnostic will repeatedly perform the operation and not print out anything until altmode is typed.

LCONI

Loop on CONI instruction (CONI 564,1 or CONI 574,1)

LCONO dat

Loop on CONO instruction (CONO 564,dat or CONO 574,dat). This writes the CSR register continuously. The data to write to CSR must be specified up to 6 octal digits.

LDATAI

Loop on DATAI instruction (DATAI 564,1 or DATAI 564,1). This may read the LAR or a CRAM location or the EBUF depending on the state of CSR bits "Test EBUF" and "Select LAR". To set up the CSR as desired just do an EEBUF or ELAR or ECRAM instruction just before this command.

LDATAO dat

Loop on DATAO instruction (DATAO 564,1 or DATAO 574,1). The data to write must be specified. This may write the LAR or a CRAM location or the EBUF depending on the state of CSR bit "Test EBUF" and the leftmost bit of the data given to write. To set up the CSR as desired just do an EEBUF or ELAR instruction just before this command.

LROUTN dat

This command allows the user to enter a routine at label DROUTN: and loop on it continuously until an altmode is typed. There are 15 locations free at DROUTN: to insert code. An octal argument is optional and is available in location "ARGUM" if typed.

10.5.3.9 Mark Bit Commands

Each CRAM word has a mark bit that can be set or cleared. It is used only to sync a scope on. Parity is not calculated for this location.

The diagnostic does not keep track of which locations have mark bits set. If it is requested to list marked CRAM locations, the diagnostic just looks for locations with the mark bit set.

Each of these commands can be given at any time without concern if the port is running or not. The diagnostic will stop the port if it has to and clear any error condition. If it changes the state of the port, the diagnostic prints a message to that effect.

MARK adr1,adr2,adr3,...

Set mark bit at locations adr1,adr2,adr3,...

RMARK adr1,adr2,adr3,...

Remove mark bit from locations adr1,adr2,adr3,...

CMARK adr1,adr2

Clear all mark bits between adr1 and adr2. If only one argument is given only that one location is rewritten without the mark bit set. If no arguments are supplied, all mark bits are cleared throughout the CRAM.

LMARK adr1,adr2

List all locations with mark bit set between adr1 and adr2. If only one argument is given only that one location is checked. If no arguments are supplied, all location with the bit set are listed throughout the CRAM.

10.5.3.10 Breakpoint Commands

A breakpoint consists of a location with bad parity. The diagnostic does not keep track of these locations itself. If it is requested to list breakpoints, it just looks for locations with bad parity.

Each of these commands can be given at any time without concern if the port is running or not. The diagnostic will stop the port if it has to and clear any error condition. If it changes the state of the port, the diagnostic prints a message to that effect.

BREAK adr1,adr2,adr3,...

Set breakpoints at locations adr1,adr2,adr3,...

RBREAK adr1,adr2,adr3,...

Remove breakpoints from locations adr1,adr2,adr3,...

CBREAK adr1,adr2

Clear all breakpoints between adr1 and adr2. If only one argument is given only that one location is rewritten with good parity. If no arguments are supplied, all breakpoints are removed throughout the CRAM.

LBREAK adr1,adr2

List breakpoints between adr1 and adr2. If only one argument is given only that one location is checked for bad parity. If no arguments are supplied, all breakpoints are listed throughout the CRAM.

PBREAK adr

Proceed from breakpoint. The address given will be used as the restart address. If none is given, the address read by the WBREAK command is used. This command causes several things to be done:

1. The CRAM location to restart at is read and rewritten with good parity.
2. The RAR is written with the start address.

3. The EBUF is written with the EBUF data read by the WBREAK command.

4. The port is restarted.

WBREAK

Assuming the port has just halted because of a CRAM PE, this command is used to print breakpoint related data - the address stopped at and the contents of the EBUF.

This command also saves this data so that a subsequent PBREAK command can be used to restart the port at the correct place, restoring the EBUF also. Note that restarting is not possible unless the instruction to restart at is an unconditional jump instruction.

10.5.3.11 Microcode Commands

Each of these commands can be given at any time without concern if the port is running or not. The diagnostic will stop the port if it has to and clear any error condition. If it changes the state of the port, the diagnostic prints a message to that effect.

Test names are given as "Test Class" "Test Number", where test class is:

- SE or S - 2910 sequencer tests
- MP or M - Mproc module tests
- AL or A - 2901 ALU tests
- CB or C - CBus module tests
- EB or E - EBus module tests

Sample test names are SE1, SE27, EB1, E1, AL20, ...

LOAD tst

Load microcode from Test "tst" into CRAM and verify the result. Example:

```
DEBUG> LOAD SE27

[Done - Number of CRAM locations loaded/verified = 17.]
```

LIST tst

List microcode from Test "tst". All locations are listed in the order that they would be loaded, not necessarily in order by CRAM address. Example:

```
DEBUG> LIST SE30

ADDR/ JUMP PAR OUT MGC SOR FUN DES CC RAM PA PB SK BUS CRY CTL  TM SP MK
   0/    2  0   0    0  0   0   0   0  0   0  0  1  0    0 CJPP  0  0  0
   1/   10  1   0    0  0   0   0   0  0   0  0  0  0    0 JMAP  0  0  0
   2/    4  1   0    0  0   0   0   0  0   0  0  3  0    0 CJPP  0  0  0
   3/   11  0   0    0  0   0   0   0  0   0  0  0  0    0 JMAP  0  0  0
   ...
```

FLOAD

Load microcode from file into CRAM. The file used is the default file name CI20.ULD or the file last specified by the SET FNAME command. DIAMON or D20MON or MAGMON must be loaded in order to load the microcode from the selected load device. The diagnostic prints an error message if it cannot access the microcode file. This command does not verify the microcode it has loaded. Example:

```
DEBUG> FLOAD

[Reading file: CI20.ULD]

[Number of CRAM locations loaded = 3040.]

[Ucode version 676]
```

FVERFY

This command causes the microcode previously loaded into CRAM from a file to be verified. Up to 4 verify errors are printed. Example:

```
DEBUG> FVERFY

[Reading ucode file: CI20.ULD]

Verify error at CRAM location 0000
 Correct: 0001 0000 1631 6702 0060
 Actual:  0000 0000 0400 0000 0000

Verify error at CRAM location 0001
 Correct: 0025 6000 4315 6542 0060
 Actual:  0000 0000 1400 0000 0040

Verify error at CRAM location 0007
 Correct: 0004 4000 7510 7542 0060
 Actual:  0000 0000 7400 0000 0340
```

```
Verify error at CRAM location 0025
 Correct: 0031 4145 4731 6723 0060
 Actual:  0000 0002 5400 0000 1240

[Number of CRAM locations verified = 3040.  Errors = 27.]
```

FLIST

List microcode in file in field format. The file used is the default file name CI20.ULD or the file last specified by the SET FNAME command. DIAMON or D20MON or MAGMON must be loaded in order to obtain the microcode from the selected load device. The diagnostic prints an error message if it cannot access the microcode file. Example:

```
DEBUG> FLIST

[Reading ucode file: CI20.ULD]

ADDR/ JUMP PAR OUT MGC SOR FUN DES CC RAM PA PB SK BUS CRY CTL  TM SP MK
   0/    2  0   0    0  1   6   3   0  0  16 16  2  0    0  CJP  0  0  0
   1/    2  1   0    0  7   5   1   0  0   0  0  2  0    0  CJP  0  0  0
   2/    7  0   1    0  4   3   1   1  0  16  0  2  0    0  CJP  0  0  0
   ...
```

FEXAM

List microcode in file in MICRO2 format. The file used is the default file name CI20.ULD or the file last specified by the SET FNAME command. DIAMON or D20MON or MAGMON must be loaded in order to obtain the microcode from the selected load device. The diagnostic prints an error message if it cannot access the microcode file. Example:

```
DEBUG> FEXAM

 [Reading ucode file: CI20.ULD]

 0000 / 0001 0000 1631 6702 0060
 0001 / 0025 6000 4315 6542 0060
 0007 / 0004 4000 7510 7542 0060
 ...
```

10.5.3.12 Miscellaneous Commands

TRANSL dat

This is used if a description of the CSR register is not at hand. The data (36 bits) is translated into English. Example:

```
DEBUG> TRANSL 3000
```

```
CSR: 000000 003000 FQErr  MVErr
```

FILLNX dat

This command fills all of CRAM with special data "J=.+1,CTL=dat". The argument specified is the control field for the microsequencer. This may be useful when testing out dispatching of the microsequencer.

If the port is running or halted with an error condition, the diagnostic stops the port and clears any error condition. If it changes the state of the port, the diagnostic prints a message to that effect.

Example: Fill CRAM with JMAP (unconditional jump) instructions:

```
DEBUG> FILLNX 2

[Number of CRAM locations loaded = 4096.]

Cram now contains:

0000/ JMAP J=1
0001/ JMAP J=2
...
7776/ JMAP J=7777
7777/ JMAP J=0
```

FILLPC dat

This command fills all of CRAM with special data "J=.,CTL=dat". The argument specified is the control field for the microsequencer. This may be useful when testing out dispatching of the microsequencer.

If the port is running or halted with an error condition, the diagnostic stops the port and clears any error condition. If it changes the state of the port, the diagnostic prints a message to that effect.

Example: Fill CRAM with JMAP (unconditional jump) instructions:

```
DEBUG> FILLPC 2

[Number of CRAM locations loaded = 4096.]

Cram now contains:

0000/ JMAP J=0
0001/ JMAP J=1
...
7776/ JMAP J=7776
7777/ JMAP J=7777
```

CCODE

This command determines the setting of each condition code and prints it out. It loads special microcode to do this but restores the original contents afterwards.

Some condition codes cannot be seen in their proper state since this command may change them. These are "CSR Changed", "MB Sign", and "F Eql Zero", but they are printed anyway. For example:

```
What test - CCODE

CC On:   CBAV FEQO CSRC MVRP PLPE CBLW
CC Off:  GCSR EBPE AFUL BFUL XATN ERQS IACT MSGN CBPE CHER
```

ESTACK

This command determines the contents of the internal 2910 microsequencer stack. It loads special microcode to do this but restores the original contents afterwards. For example:

```
What test - ESTACK

2910 Stack:
 Location   Contents (addr)
    Top         3042
    -1           733
    -2           140
    -3          5732
    -4            10
```

ENEXT

ENEXT does an "examine next" function. Whatever examine or deposit operation was previously done, the next location or register is examined. The commands which set up for an examine next are: ECRAM, DCRAM, BCRAM, ACRAM, ZCRAM, LCRAM, E2901, D2901, Z2901, ELOCS, DLOCS, and ZLOCS.

DNEXT arg

DNEXT does an "deposit next" function. Whatever examine or deposit operation was previously done, the data given is deposited into the next location or register. No argument is expected on the BCRAM or ACRAM type of deposit, the data for each field of the microword will be queried. The commands which set up for an examine next are: ECRAM, DCRAM, BCRAM, ACRAM, ZCRAM, LCRAM, E2901, D2901, Z2901, ELOCS, DLOCS, and ZLOCS.

IPRINT

This command prints accumulated interrupt activity. The data for up to 20 interrupts are held in an interrupt data table. This data can be printed with this command.

Printing can be aborted by typing an altmode or suppressed by typing a Control-O.

ICLEAR

This command clears the accumulated interrupt activity. Subsequent interrupts are numbered 1,2,...

IINIT

In the event the PI system got shut off in exec mode, this command may be given to initialize the interrupt system and set up 40+2n addresses. This may be useful in the event the diagnostic shuts off the PI system because of too many interrupts - this occurs after 8192 interrupts.

10.5.3.13 Data Transfer Commands

RDINIT

This command performs initialization in preparation for a read (port writing into KL10 memory). The diagnostic builds a CCW list that will transfer the number of words specified by the last SET LEN command. It also initializes the buffer by filling it with the data pattern "400000,,000001".

WRINIT

This command performs initialization in preparation for a write (port reading KL10 memory). The diagnostic builds a CCW list that will transfer the number of words specified by the last SET LEN command. It also initializes the buffer by filling it with the data pattern selected by the last SET PAT command.

BPRINT n

This command prints buffer contents (n locations). If no length is specified the diagnostic prints the entire buffer the length of which is determined by a previous SET LEN command. For example:

```
| DEBUG> BPRINT 7
|
| Wrd 0.  777777 777777   777777 777777   777777 777777   777777 777777
| Wrd 4.  777777 777777   777777 777777   777777 777777
```

CCWPNT

This command prints the CCW list last generated by a RDINIT, WRINIT, or START command. Example:

```
DEBUG> CCWPNT

CCW List:
  #  Op Code     Word Cnt  Buffer Adr     This data transfer is 100000
  -  -------     --------  ----------     words long.  The buffer is
  1  Dt-fwd         512    00047000       only 512 words long so the
 ..                                       buffer address remains the
304  Dt-fwd-hlt     160    00047000       same for the entire transfer.
```

LOGPNT

This command prints the logout data last stored by the channel upon receipt of the "store" command issued by the microprocessor. Example:

```
DEBUG> LOGPNT

Channel-7 Logout Data
Loc    Contents
 1     ICW: 000000 000000
 2     SW1:    CLP points to: 0
 3     Last Updated CCW: 000000 000000    WC=0.  ADR=0
```

COMPAR

Compare data buffer. The data compare is done based on the word count set up earlier by a SET LEN command. Normally a data compare could be done after running some microcode which did a data transfer. No data comparisons are done unless the diagnostic is specifically requested to do so. Example:

```
DEBUG> COMPAR

Data Compare Error:
Word     --Correct Data--       ---Actual Data--
    2       525252 525252          400000 000001
    4       525252 525252          400000 000001
    6       525252 525252          400000 000001
Words in error = 64.
```

10.5.3.14 Switches

SWITCH

Enter switch information. Switches can be entered as in the following example. Usually, though, it is easier just to type the switch name to turn on or off a switch.

```
DEBUG> SWITCH

Print the selectable pgm switches? (Y or N) - Y

----Left Side Switches--------   ----Right Side Switches--------

SW   KL10     11    Function      SW   Value  Function
--   ----    ----   --------      --   -----  --------
 0  400000  100000  Abort         18  400000  Program trace
 ...

Switches = 020010 004000

20010  LH Switches <# or ?> - ?

Type  Y,N,^,CR,^Z

N ABORT -
N RSTART -
...

4000  RH Switches <# or ?> - ?

Type  Y,N,^,CR,^Z

N TRACE -
N INHFLT -
...
```

SWPRIN

Print current switch settings. Example:

```
DEBUG> SWPRIN

Switches:  020010 002000   PNTLPT OPRSEL UDEBUG
```

```
NOPNT    RELIAB   TRACE    DSPEAR   UDEBUG
PNTLPT   TXTINH   INHFLT   NIPORT   MDEBUG
DING     OPRSEL   INHMSG   CIPORT   SDEBUG
LOOPER            LOOPGM   MPROC    LDEBUG
ERSTOP            LOOPTS   MCBUS
PALERS            RUNALL
```

The name of each of these switches can be typed. The result is to complement the switch setting. If left hand switches are typed in exec mode an error message is printed.

11.0 PROGRAM RUN TIME

The run time varies according to the sequence of tests chosen, the test options selected, and the program switch options selected.

In default mode the run time is approximately 3 minutes per port per pass, excluding any time taken to print error messages. The diagnostic runs slightly faster in exec mode. If the "OPRSEL" switch is not used, each port will run 5 passes, bringing the total run time to around 28 minutes in user mode (24 minutes in exec mode).

Running all of the tests with "RELIAB" switch set extends the time by a factor of 4, to around 2 hours.

```
---------------------------------------------------------------------------
VERSION:        MAINDEC-10-DFPTA-A      Version 0.1

AUTHOR:         Richard Stockdale

DATE:           December 31, 1983

REASON:         Original release.
---------------------------------------------------------------------------
VERSION:        MAINDEC-10-DFPTA-B      Version 0.2

AUTHOR:         Richard Stockdale

DATE:           December 31, 1984

REASON:         Added support for TOPS10 usermode operation.
```

VERSION: MAINDEC-10-DFPTA-C Version 0.3

UPDATE AUTHOR: Gregory A. Scott

DATE: May, 1985

REASONS:

Added title statements to each module for DDT typeout of module that this symbol is defined in.

Fix TOPS-10 usermode operation: Don't check TOPS-20 privs on the -10. Use proper DIAG. UUO function. Trust setting of MONTYP rather than try and figure it out again. Print "Exec Only Test" rather than "Ommitted". Add proper TOPS-10 error codes to T10TAB. Use monitor uptime instead of time of day for timing operations.

Change strange output of help messages (using several ASCII psuedo-ops padded by spaces to word boundries followed by an ASCIZ, depends on literal pool not being rearranged by MACRO) to big ASCIZ string, add .DIRECTIVE FLBLST to clean listing.

Fix error message if port not available to indicate to operator what command is needed to free the port for diagnostic use.

If DFPTA was running the one port on one job, and another DFPTA wanted to run the other port, the second copy of DFPTA would "hang" trying to determine what ports existed. This was because the monitor makes a second diagnostic wait for the port rather than returning an error like "another job owns the port". Now if the switches CIPORT and NIPORT are on, we onlu look for that type of port, enabling paralell operation of both CI and NI.

VERSION: MAINDEC-10-DFPTA-D Version 0.4

UPDATE AUTHOR: Gregory A. Scott

DATE: July 1, 1985

REASONS:

If run without OPRSEL on the diagnostic would exit before releasing the port to the operating system. If any diagnostic is run later which tried to use the port it would "hang" trying to get the port again.

Output of "End pass" messages was incorrect. Always print them rather than trying to print them based on various conditions.

Output "?" in front of error message for batch runs.

        3250     DHELP - Print DEBUG> help message
        3419     DSET - Set/clear/print options
        3466     DSETAD - Set start address for START/SSTEP/CONT commands
        3492     DSETCS - Set start CSR data for START/CONT commands
        3511     DSETPR - Set/clear automatic parity generation for load cram command
        3535     DSETEB - Set/clear preserve EBUF for single stepping
        3558     DSETLN - Set length of data transfer
        3583     DSETDA - Set data pattern to insert in buffer
        3626     DSETFN - Set default microcode file name
        3656     DSETWH - Print all selected options
        3674     DSETFA - Set failing network
        3718     DSETPL - List data patterns
        3763     DSETHE - Set help message
        3792     Program Flags
        3807     DECSR - Examine CSR register
        3821     DDCSR - Deposit CSR register
        3836     DZCSR - Zero CSR register
        3848     DCONI - Loop on CONI's
        3861     DCONO - Loop on CONO's
        3878     DDATI - Loop on DATAI's
```

3891 DDATO - Loop on DATAO's
3907 DROUTN - Routine to do special diagnostic loop
3936 DRESET - Issue an EBUS Reset
3947 DCLEAR - Issue a 'Port Clear'
3957 DSINIT - Set up start addr/data/history prior to single step command
3973 DSTART - Start the port
4018 DSTOP - Stop the port
4048 DSSTEP - Single step the port
DTRACE - Single step the port and trace progress
4148 DSSPNT - Print single step history
4172 DSSCLR - Clear single step history data
4193 PNTHST - Print a single step history entry
4216 SAVHST - Save single step history data
4239 DCONT - Continue the port
4267 DEEBUF - Examine EBUF register
4289 DDEBUF - Deposit EBUF register
DZEBUF - Zero EBUF register
4316 DELAR - Examine LAR register
4337 DDRAR - Deposit RAR register
4355 DZRAR - Zero RAR register
4368 DECRAM - Examine CRAM locations specified by 'PARG1' and 'PARG2'.
4376 DDCRAM - Change CRAM locations.
4384 DBCRAM - Change CRAM locations by field
4392 DACRAM - Alter CRAM locations.
4400 DZCRAM -- Zero CRAM addresses specified.
4408 DLCRAM -- List CRAM addresses specified.

4995 DEALU - Examine 2901 registers
5097 DDALU - Deposit register
5174 DZALU - Zero 2901 registers
5285 DELOCS - Examine local storage
5388 DDLOCS - Deposit local storage
5460 DZLOCS - Zero local storage
5569 DMARK - Set mark bit in CRAM locations
5612 DRMARK - Remove mark bit in CRAM locations
5655 DCMARK - Clear all mark bits
5728 DLMARK - List locations with mark bit set
5814 DENEXT - Examine next
5879 DDNEXT - Deposit next
5930 DESTAK - examine 2910 stack
5983 DBREAK - Set breakpoint
6034 DRBRK - Remove breakpoint
6073 DCBRK - Clear all breakpoints
6141 DLBRK - List breakpoints
6230 DLOAD - Load microcode into CRAM from a test.
6265 DLIST - List microcode from test
6294 DFLOAD - Load microcode from file into CRAM
6330 DFVERF - Verify microcode from file versus CRAM
6392 DFLIST - List microcode in file
6421 DFEXAM - Examine microcode in file
6450 DTRANS - Translate CSR bits to English
6465 DCCODE - Print condition codes

```
        6558    DFILLN - Fill CRAM with special data (J=PC+1,OPCode)
        6585    DFILLP - Fill CRAM with special data (J=PC,OPCode)
        6609    DRDINI - Initialize everything for a read
        6636    DWRINI - Initialize everything for a write
        6646    DBPNT - Print buffer contents
        6679    DCWPNT - Print CCW list
        6690    DLGPNT - Print logout data
        6704    DCOMPA - Compare data buffer
        6724    DSWIT - Switch complement commands
        6738    IPRINT - Print interrupt history
        6794    IINIT - Initialize interrupt system

        *****************************************************************
6804    Program Utility Routines
        *****************************************************************

        6807    TRACE - Program Trace Routine
        6876    TSTGET - Get test related data based on test dispatch address
        6915    SELTST - Select a test to run.
        6947    CHKTST - Check if this is a valid test to execute and set up test type.
        6992    TSTPNT - Print test name/number
        7014    ODELAY - Delay a specified amount of time (in milliseconds in AC0)
        7050    DDELAY - Delay a specified amount of time (in milliseconds in AC0)
        7077    MLOADN - Load microcode and verify it (do not print errors)
                MLOADY - Load microcode and verify it (print errors)
        7208    MVPNT - Print verify error data
        7257    MLIST - List microcode of a test
        7293    PNTCRM - Print CRAM word
```

```
          7376     PNTWD - Print a CRAM word (xxxx xxxx xxxx xxxx xxxx)

          7400     CALPAR - Calculate parity for a CRAM location

          7449     TLOAD - Load microcode/verify it for a test

          7497     CSRPNT - Print CSR register as 'CSR: xxxxxx,,xxxxxx' followed by
                            English translation.

          7515     CSRENG - Print CSR data in English

          7547     CSRENB - CSR bits

          7594     SAVCRM - Save specified CRAM locations in a buffer

          7612     RESCRM - Restore CRAM locations

          ***************************************************************
7635      SPEAR Reporting
          ***************************************************************

          7638     SPREP1 - Print initial SPEAR report 'diagnostic started'

          7691     SPREP2 - Print error or successful completion SPEAR report

          7820     GETPPN - Find out PPN number

          ***************************************************************
7832      Test Execute Routines
          ***************************************************************

          7835     SEXEC - Execute entries in a 'Single Step Table'

          8048     SSPNT - Print out single step data that resulted in an error

          8095     AEXEC - ALU type test execute routine

          8226     AAPNT - Print results message

          8282     BEXEC - Execute entries in a 'Single Step Table', verifying EBUF data

          8516     BBPNT - Print out single step data that resulted in an error

          8591     TEXEC - Test execute routine

          8851     TTPNT - Print out error data

          8911     CEXEC - Data test execute routine
```

```
                9282    CCPNT - Print out error data
                9373    IEXEC - Interrupt test execute routine
                9891    IIPNT - Print out error data

                ******************************************************************
         10066  Miscellaneous Test Variables
                ******************************************************************

                10118   Data Buffer Areas For Reading And Writing
                10127   Data transfer paramters
                10147   Special code to test SPEAR entries
                10187   Special code to produce an EXE version

                ******************************************************************
         2      EBUS Module Tests
                ******************************************************************

                48      TEST 1 - Is there an port out there?
                97      Test 2 - RH20/Port Interaction
                201     Test 3 - RH20/Port Interaction
                302     Test 4 - RH20/Port Interaction
                406     Test 5 - RH20/Port Interaction
                506     Test 6 - CSR Cleared After Reset
                568     Test 7 - Read/Write CSR Bits
                733     TEST 10 - CSR Bits Interaction
                833     TEST 11 - EBUF Access Test
                887     TEST 12 - EBUF/CSR Conflict Test
                948     TEST 13 - KMUX Parity Generators
                1092    TEST 14 - EBUF/CSR Conflict Test
                1176    TEST 15 - EBUF Reset Test
                1241    TEST 16 - EBUF Data Path Test
```

1400 TEST 17 - CSR Bit 18 Self Clearing Test
1450 TEST 20 - CSR Bit 18 Reset Test
1501 TEST 21 - CSR Bit 18 Reset Test
1559 TEST 22 - Read/Write EBUF When Ucode Running
1654 TEST 23 - Par Gen - Not Forcing an Error
1839 TEST 24 - Par Gen - Forcing an Error
1929 TEST 25 - Read only CSR Bits
2031 TEST 26 - CSR 01 'DIAG RQST CSR'
2117 TEST 27 - CSR 01 'DIAG RQST CSR'
2207 TEST 30 - CSR 01 'DIAG RQST CSR'
2291 TEST 31 - CSR 01 'DIAG RQST CSR'
2378 TEST 32 - CSR 01 'DIAG RQST CSR'
2457 TEST 33 - CSR 01 'DIAG RQST CSR'
2541 TEST 34 - CSR 02 'DIAG CSR CHNG'
2643 Test 35 - Constant MUX
2877 Test 36 - Constant MUX Interference
2965 TEST 37 - CSR Bit 24 - EBUS PE Occurs at Wrong Time
3022 TEST 40 - EBUS Transfer via DATAO's
3145 TEST 41 - EBUS Transfer via DATAI's
3301 TEST 42 - CSR 05 'Rqst Interrupt'
3379 TEST 43 - CSR 05 'Rqst Interrupt'
3455 TEST 44 - CSR 05 'Rqst Interrupt'
3531 TEST 45 - CSR 06 'CRAM Par Err'
3605 TEST 46 - CSR 07 'MBUS Err'
3685 TEST 47 - CSR 11 'Idle' Bit

3907 TEST 50 - CSR 12 'Disable Complete' Bit
4128 TEST 51 - CSR 13 'Enable Complete' Bit
4347 TEST 52 - x
4359 TEST 53 - MPROC Run Bit
4436 TEST 54 - Basic KMUX Parity Test
4528 TEST 55 - Clearing MPROC Run Bit
4611 TEST 56 - Clearing MPROC Run Bit
4689 TEST 57 - Verify 'Diag Single Cyc'
4765 TEST 60 - PI Level n/0 Interrupts
4949 TEST 61 - Check PIA Level 0
5046 TEST 62 - Check Interrupt on Level 1-7
5173 TEST 63 - CSR 05 'Rqst Interrupt' Clearing
5293 TEST 64 - IOP Function 0 - 40+2N Interrupt
5565 TEST 65 - IOP Function 1 - 40+2N Interrupt
5836 TEST 66 - x
5849 TEST 67 - x
5861 TEST 70 - IOP Function 4 - Examine
6120 TEST 71 - IOP Function 5 - Deposit
6385 TEST 72 - IOP Function 7 - Examine/Increment
6642 TEST 73 - CSR 25-26 & 28 KL-side
6845 TEST 74 - CSR 25-26 & 28 Port-side
7067 TEST 75 - CSR 27 & 30-31 KL-side
7233 TEST 76 - CSR 27 & 30-31 Port-side

       2       Port Controller Utility Package
               ***************************************************************

               ***************************************************************
       60      Port Register Read/Write Routines
               ***************************************************************
               63      Notes On I/O Routine Design
               113     Port Register Load Routines
               125     LDEBUF - Load EBUF
               142     LDCSR - Load CSR (This is simply a CONO).
               156     LDRAR - Load RAR
               180     LDCRAM - Load CRAM
               199     Port Register Read Routines
               216     RDEBUF - Read EBUF
               233     RDCSR - Read CSR
               251     RDLAR - Read LAR
               275     RDCRAM - Read CRAM
               293     .CONI - Do a simple CONI (no error checking)
               313     .CONO - Do a simple CONO
               333     .DATAI - Do a simple DATAI (no error checking)
               353     .DATAO - Do a simple DATAO
               372     ERESET - Issue an EBUS reset
```

```
        *****************************************************************
383     Port Specific Utility Routines
        *****************************************************************

        386     ISTOP - Stop IPA either by a port clear or by clearing the CSR register

        431     IPACLR - Issue a port clear

        442     SETEBU - Check that 'Diag Test EBUF' bit is set in CSR and set if not.

        462     SETLAR - Check that 'Diag Sel LAR' bit is set in CSR and set if not.

        481     CLREBU - Check that 'Diag Test EBUF' is not set in CSR and clear if is.

        500     CHKCSR - Check if error bits are set in the CSR register

        529     IPASRT - Start the port at the address given in 'SADDR' and with
                         initial parameters given in 'SDATA'.

        609     IPASTP - Stop the port

        673     IPASST - Single step the port at the address given in 'SNEXT' and
                         with initial parameters given in 'SDATA'.

        *****************************************************************
776     PI System Routines
        *****************************************************************

        779     INITPI - Initialize and Turn On PI System

        820     .PIOFF - Detach port from PI system

        836     .PION - Attach port to PI system (Channel 4)

        854     PISYOF - Turn PI system off

        863     PISYON - Turn PI system on

        871     SETVEC - Set up interrupt vectors for an port under test

        895     SET2N - Set up 40 + 2N locations with interrupt dispatch instruction

        917     VIINT - Vectored interrupt (Port)

        982     NVIINx - Non-Vectored interrupt (Port)

        1132    .INPNT - Print special interrupt data
```

```
         *****************************************************************
  1179   Page Fail Handling Routines
         *****************************************************************

         1182     PFSET - Set up EPT locations 500-502 to handle page fails

         1215     PFCLR - Restore EPT locations 500-502 to original values

         1229     PFCHK - Check reason for page fail and dispatch appropriately

         *****************************************************************
  1265   Channel Handling Routines
         *****************************************************************

         1268     Routines To Interface With A Channel

         1304     CHINIT - Channel Initialization Routine

         1360     GENCCW - Channel Command Word Generator

         1508     GRINDF - Subroutine to build a forward transfer CCW list.

         1534    ******** Next 2 instructions are ommitted for DFPTA tests. ****************
                 ******** This causes every CCW to start at same memory location. **********

         1559     CCWST - RH20 CCW Store Routine

         1585     GETLOG - Snapshot The Channel Logout Area

         1621     LOGPNT - Channel Logout Printer

         1693     CCWPNT - Channel Command List Printer

         1781     CHP20 - Builds a TOPS20 User Mode Channel Program

         1844     CHP10 - Builds a TOPS10 Channel Command List

         1896     DIAGER - Report Monitor Call Error In User Mode

         1918     Some Channel Routine Variables

         1949     CHDATA - Obtain channel logout data and inspect results
         ******************************************************************
1970     User Mode Support Routines
         ******************************************************************

         1973      DSETUP - Setup Routine For Diagnostic Function

         2037      CPUTST - Determine Which Of 2 CPU's To Run On

         2078      DEVREL - User Mode Release Routine

         2206      DEVREQ - User Mode Request Routine

         2359      DGEPNT - Decode and print DIAG error

         2408      USRION/USRIOF - Turn User I/O Privileges On/Off

         2437      ENABLE - Enable Capabilities of This Process

         ******************************************************************
2455     Miscellaneous Routines
         ******************************************************************

         2458      FFF - Routine To Handle Fatals

         ******************************************************************
2        UTILITY Routines Module
         ******************************************************************

         ******************************************************************
66       Printout/Typin Routines
         ******************************************************************

         69        CONVSX - Convert sixbit to octal

         109       ALTCHH - Handle altmode intercept

         134       CLRBUF - Clear input buffer

         149       TTYYES - Answer yes or no question

         177       PSDN - Prints signed decimal numbers

         202       .PNTOC - Print n digit octal number with leading zeros suppressed

         240       PPDEC - Print decimal number in a field of size x.

         276       PPDECF - Force print decimal number in a field of size x.
```

```
              *****************************************************************
      311     Clock Handling Routines
              *****************************************************************

              314      STCLOK - Initialize program runtime clock

              354      MONTIM - Read program runtime from monitor

              393      PTIME - Print time of day

              411      RUNTME - Calculate and print program runtime

              517      PSTAMP - Check for an 'S' typed.

              559      LSTAMP - Check for an 'S' typed.

              *****************************************************************
      591     TOPS10/20 Related Routines
              *****************************************************************

              594      .RESET - Subroutine to issue a RESET JSYS/UUO

              610      .CLOSE - Subroutine to close opened files

              638      .EXIT - Subroutine to exit job in user mode

              *****************************************************************
      667     File Handling Routines
              *****************************************************************

              670      FINIT - Initialize reading of microcode file

              696      CHRIN - Routine to read an ASCII character from the selected file.

              706      CHRINS - Routine to read an ASCII character from the selected file.

              733      FFAIL - Routine to report '"DIAMON"' open failure on a selected file.

              751      FGETW - Get microword entry from file

              797      FGETA - Obtain microcode load address 'ADDR:' from file

              824      FGETD - Obtain microcode data entry from file (4 digits).
```

```
        ******************************************************************
 850    Data Pattern Generator/Compare Routines
        ******************************************************************

        853      BUFGEN - Generate the specified data pattern in the data buffer.
                 BUFCOM - Compare the data buffer with expected data

        989      DATMES - A data comparison error has been found.  Report the error,
                 printing a maximum of three lines of errors.

        ******************************************************************
 1029   Data Patterns
        ******************************************************************

        1032     Data Patterns

        1209     PATPNT - Translate pattern number to description

        ******************************************************************
 1301   Switch Handling Routines
        ******************************************************************

        1304     .SWCHP - Print switch settings in English

        1370     SWITT - Get value of switches

        1383     .ISWT - Complete switch handling

        1476     .SLEFT - Input left hand switches

        1539     .SRIGT - Enter right hand switches

        1708     SWCHPT - Prints current state of switches

        1720     SWCOM - Switch complement routine (AC1 has switch command number 0-n)

        ******************************************************************
 1821   Miscellaneous Routines
        ******************************************************************

        1824     PARSER - Additional CPU parity error service

        1871     .COMM - Match a command entered against a command table.

        1919     .COMM2 - Compare command typed to table to see if valid

        1951     .SARG - Obtain SIXBIT argument

        2037     .OARG - Obtain octal argument
```

```
          2126    DECYN - Decode an argument which should be NO or YES
          2152    .DARG - Obtain octal/decimal argument
          2244    CHKARG - Check for argument when there shouldn't be any
          2289    LASARG - Check for last argument when there shouldn't be any more
          2330    FIOFF - Routine to turn off the 'file input' switch
          2348    FINCMD - Input a sixbit command from a file
          2395    FSARG - Input a sixbit argument from a file
          2442    FOARG - Input a octal argument from a file
          2503    FEOL - Skip characters until end of line is reached

          ******************************************************************
     2514 Scope Looping And Error Reporting Routine
          ******************************************************************

          2517    SCOPE1 - Error reporter and scope loop controller
```

```
                                        SUBTTL  DFPTA TITLE FILE

;* Microword Field Definitions
;
;  These definitions are arranged for the macro which generates pairs
;  of microwords as (addr & parity flags & left 20 bits,right 36 bits).
;  These are of the form:
;
;  Word 1:  Bits 00-11 - Microword load address (0000-7777)
;                12-35 - Bits 0-23 of microword to load
;  Word 2:  Bits 00-34 - Bits 24-57,59 of microword to load
;                35 ---- Force Bad Parity flag
;
;  In detail:
;
;  Word 1:  Bits 00-11 - Microword load address
;                12-23 - MWJMPFLD
;                24    - MWPAR
;                25    - MWOUTPUTENA
;                26-35 - MWMGCFLD
;
;  Word 2:  Bits 00-02 - MWSORCEFLD
;                03-05 - MWFUNCTFLD
;                06-08 - MWDESTFLD
;                09    - MWCCENA
;                10    - MWRAMODE
;                11-14 - MWPORTAFLD
;                15-18 - MWPORTBFLD
;                19-23 - MWSKIPFLD
;                24-26 - MWBUSCTLFLD
;                27    - MWCARRY
;                28-31 - MWCTRLFLD
;                32    - MWTIMEFLD
;                33    - MWSPARE00
;                34    - MWMARKBIT
;
;                35    - Force bad parity flag
;
;  The microwords are generated using a set of field  definitions
;  describing how the two words are to be constructed. Each field
;  is defined as a bit position in the first word, a bit position
;  in the right word, and a magnitude describing the size  of the
;  field.  These are defined as follows:
;
;      .Lxxxx - Specifies the rightmost bit position of the field
;               in the left word. If the field does not appear in
;               left word, this will be zero.
;
;      .Rxxxx - Specifies the rightmost bit position of the field
;               in the right word.  If the field  does not appear
;               in right word, this will be zero.
;
;      .Mxxxx - Specifies the maximum magnitude of the  field  in
;               the word.
```

```
                                        ;  The microwords are generated as follows:
                                        ;
                                        ;  Left word = ((value AND .Mxxxx) times .Lxxxx) ! next field ...
                                        ;  Right word = ((value AND .Mxxxx) times .Rxxxx) ! next field ...
                                        ;
                                        ;  Parity is calculated prior to loading into the CRAM.  The parity
                                        ;  bit  may be specified explicitly by specifying EVEN or ODD.  The
                                        ;  microcode  loader  will  ensure  that the word has the specified
                                        ;  parity.  If not specified, the correct parity will be calculated.
                                        ;
                                        ;  Sample microword definitions:
                                        ;

                SUBTTL  Test Execute Routines

;#***********************************************************************
;* SEXEC - Execute entries in a 'Single Step Table'
;
; This routine is used to simplify the coding of micro-diagnostic tests
; which single step the microsequencer and which normally  pass or fail
; depending on the CRAM address latched into the Latch Address Register
; at various points in the test.
;
; This routine is given a pointer to the 'Single Step Table'.  It then
; executes one entry and returns +1,+2,+3 or +4 depending  on the type
; of entry and the result.
;
; Argument:     AC6 - Address of 'Single Step Table'
;
; Return:       +1 - End of table was seen.
;               +2 - A routine was called, and this entry has completed.
;               +3 - The single steps are done but final address incorrect
;               +4 - The single steps are done and final address correct
;
;               NSSTEP - Contains number of single steps done
;               SSADDR - Initial starting address
;               SEADDR - Correct final address
;               SAADDR - Actual final address
;
;               AC6 - Updated to point to the next table location
;
; Single Step Table Format:
;
;               Entry
;               Entry
;               ...
;               SSLAST          ; last entry (zero)
;
; 'Entry' is of the form:
;
; Bits 0-2 - Type of entry - 0 - Single Step (start addr given)(SSSTRT)
;                            1 - Single Step (continue)         (SSCONT)
;                            2 - Special Call                   (SSCALL)
;                            3 - Special Call, pass/fail exit   (SSCHK)
;                            4 - Select new table address       (SSJRST)
```

```

; Bits 3-35 - Defined per entry type.
```

```

```
;#**********************************************************************
;* BEXEC - Execute entries in a 'Single Step Table', verifying EBUF data
;
; This routine is used to simplify the coding of micro-diagnostic tests
; which single step the microsequencer and which normally  pass or fail
; depending  on  the result stored in the EBUF at various points in the
; test.
;
; This routine is given a pointer to the 'Single Step Table'.  It then
; executes one entry and returns +1,+2,+3 or +4 depending  on the type
; of entry and the result.
;
; Argument:      AC6 - Address of 'Single Step Table'
;
; Return:       +1 - End of table was seen.
;               +2 - A routine was called, and this entry has completed.
;               +3 - The single steps are done but EBUF data incorrect
;               +4 - The single steps are done and EBUF data correct
;
;                NSSTEP - Contains number of single steps done
;                SSADDR - Initial starting address
;                SEADDR - Correct final address
;                SAADDR - Actual final address
;                CEBUF - Correct final EBUF data
;                AEBUF - Actual final EBUF data
;                BFLAG - flag - error address (0 ok, -1 incorrect)
;
;                AC6 - Updated to point to the next table location
;
; Single Step Table Format:
;
;                Entry
;                Entry
;                ...
;                SSLAST          ; last entry (zero)
;
; 'Entry' is of the form:
;
; Bits 0-2 - Type of entry - 0 - Single Step (start addr given)(SSSTRT)
;                            1 - Single Step (continue)        (SSCONT)
;                            2 - Special Call                  (SSCALL)
;                            3 - Special Call, pass/fail exit  (SSCHK)
;                            4 - Select new table address      (SSJRST)
;
```

```
; Bits 3-35 - Defined per entry type.

;#***********************************************************************
;* TEXEC - Test execute routine
;
; This routine starts up the port and reads CSR register  to find
; out the results of tests performed by microcode.  It  may  also
; stop the port to read the EBUF and verify its contents.
;
; This  routine is given a pointer to a 'Test Execute Table'.  It
; then executes one entry and returns +1,+2,+3 or +4 depending on
; the type of entry and the result.
;
; Argument:     AC6 - Address of 'Test Execute Table'
;
; Return:       +1 - End of table was seen.
;               +2 - A routine was called (just do next entry).
;               +3 - Error return.
;               +4 - Success return.
;
;               TADDR - Initial starting address

;*************************************************************************
;* CEXEC - Data test execute routine
;
; This routine is used to execute a CBUS data transfer type test.  It
; allows data transfers to be set up, specifying buffer  lengths  and
; data pattern.  It can set up and start a data transfer, and inspect
; the result, and do data compare of the resulting buffer.
;
; This routine is given a pointer to a 'Data Test Execute Table'.  It
; then executes one entry and returns +1,+2,+3 or +4 depending on the
; type of entry and the result.
;
; Argument:     AC6 - Address of 'Data Test Execute Table'
;
; Return:       +1 - End of table was seen.
;               +2 - A routine was called (just do next entry).
;               +3 - Error return.
;               +4 - Success return.
;
;               QADDR - Initial starting address
;               QADDRF - Final address
;               CTIME - Amount of time to let port run
;               CEBUFC - Correct EBUF data
;               CEBUFA - Actual EBUF data
;               CPAT - Data pattern used
;               CLEN - Buffer length
;               CTRAN - Type of transfer 0-none,1-rd,2-wr,3-rd/wr
;               CDERR - Data compare error - 0-no,-1-yes
;               CSERR - Status error - 0-none,xx-error bits
;
;               AC6 - Updated to point to the next table location
;
; Test Execute Table Format:
;
;               Entry
;                ...
;               CLAST           ; last entry (zero)
;
; 'Entry' is of the form:
;
; Bits 0-3 - Type of entry
;    0 - Done with table (CLAST)        6 - Call routine (test exit) (CCALLC)
;    1 - Set up read DT  (CSETRD)       7 - Wait for dt completion   (CWAIi)
;    2 - Set up write DT (CSETWR)      10 - Compare data buffer      (CCOMP)
;    3 - Set up rd/wr DT (CSETRW)      11 - Select new table address (CJRST)
;    4 - Start port      (CSTART)      12 - Exit test (if erflg set) (CEXIT)
;    5 - Call routine    (CCALL)
```

```
; Bits 4-35 - Defined per entry type.
;
;     Entry type 0 (CLAST) -  All zero - indicates end of table
```

```
                                  ; Bits 4-35 - Defined per entry type.

```

```
;*************************************************************************
;* IEXEC - Interrupt test execute routine
;
; This routine is used to execute a interrupt type test.  It  allows
; the interrupt system to be set up and interrupts to be fielded.
;
; This  routine  is  given  a  pointer  to an 'Interrupt Test Execute
; Table'.  It  then  executes  one  entry  and returns +1,+2,+3 or +4
; depending on the type of entry and the result.
;
; Argument:     AC6 - Address of 'Interrupt Test Execute Table'
;
; Return:       +1 - End of table was seen.
;               +2 - A routine was called (just do next entry).
;               +3 - Error return.
;               +4 - Success return.
;
;               IADDR - Initial starting address
;               IADDRF - Final address
;               ICSR - Final CSR data
;               ITIME - Amount of time to let port run
;               IFLAG - Interrupt should occur data
;                 bits 0-2 - IOP function
;                            0 - non-vectored
;                            1 - vectored
;                            2 - examine
;                            3 - deposit
;                            4 - increment
;                            5 - decrement
;                            6 - examine/increment
;                 bits 3-8 - type of interrupt
;                            0 - vectored
;                            1 - non-vectored on PI level 1
;                            .         ...         ...
;                            7                          7
;                           77 - no interrupt should occur
;                 bits 9-35 - address to execute (for vectored
;                             or non-vectored interrupts) or the
;                             location to increment, decrement,
;                             examine, or deposit
;               IITYPE - Type of interrupt which occurred
;                           -1 - none
;                            0 - vectored
;                            1 - non-vectored on PI level 1
